TABLE OF CONTENTS

UNITED STATES OF AMERICA
BEFORE THE
FEDERAL ENERGY REGULATORY COMMISSION

North American Electric Reliability Corporation	))	**Docket No. ________**

PETITION OF THE NORTH AMERICAN ELECTRIC RELIABILITY CORPORATION FOR APPROVAL OF PROPOSED RELIABILITY STANDARD TPL-001-5

Pursuant to Section 215(d)(1) of the Federal Power Act ("FPA")[1] and Section 39.5[2] of the Federal Energy Regulatory Commission's ("FERC" or "Commission") regulations, the North American Electric Reliability Corporation ("NERC")[3] hereby submits for Commission approval proposed Reliability Standard TPL-001-5 – Transmission System Planning Performance Requirements. As discussed more fully herein, proposed Reliability Standard TPL-001-5 improves upon currently effective Reliability Standard TPL-001-4 by providing for more comprehensive and robust planning studies, thereby improving reliability. Further, the proposed standard addresses certain Commission directives from its Order No. 786 approving TPL-001-4.[4] NERC requests that the Commission approve the proposed Reliability Standard (**Exhibit A**) and find that the proposed standard is just, reasonable, not unduly discriminatory or preferential, and in the public interest. NERC also requests that the Commission approve: (i) the associated Implementation Plan (**Exhibit B**); (ii) the associated Violation Risk Factors ("VRFs") and

---

[1] 16 U.S.C. § 824o (2018).

[2] 18 C.F.R. § 39.5 (2018).

[3] The Commission certified NERC as the electric reliability organization ("ERO") in accordance with Section 215 of the FPA on July 20, 2006. *N. Am. Elec. Reliability Corp.*, 116 FERC ¶ 61,062 (2006), *order on reh'g & compliance*, 117 FERC ¶ 61,126 (2006), *aff'd sub nom. Alcoa, Inc. v. FERC*, 564 F.3d 1342 (D.C. Cir. 2009).

Violation Severity Levels ("VSLs"), which remain unchanged from TPL-001-4 (**Exhibit D**); and (iii) the retirement of currently effective Reliability Standard TPL-001-4.

As required by Section 39.5(a)[5] of the Commission's regulations, this Petition presents the technical basis and purpose of the proposed Reliability Standard, a demonstration that the proposed Reliability Standard meets the criteria identified by the Commission in Order No. 672[6] (**Exhibit C**), and a summary of the standard development history (**Exhibit G**). The proposed Reliability Standard was adopted by the NERC Board of Trustees on November 7, 2018.

This Petition is organized as follows: Section I of the Petition presents a summary of the proposed Reliability Standard. Section II of the Petition provides the individuals to whom notices and communications related to the filing should be provided. Section III provides background on the regulatory structure governing the Reliability Standards approval process. This section also provides information on the development of the proposed Reliability Standard through Project 2015-10 – Single Points of Failure TPL-001 and the Commission orders and NERC activities that informed its development. Section IV of the Petition provides a detailed discussion of the proposed Reliability Standard and explains how the proposed standard enhances reliability by providing for more comprehensive consideration of Protection System[7] single points of failure, known outages, and the unavailability of long lead-time equipment in planning studies. Section V of the Petition provides a summary of the proposed implementation plan.

---

5 18 C.F.R. § 39.5(a).

6 The Commission specified in Order No. 672 certain general factors it would consider when assessing whether a particular Reliability Standard is just and reasonable. *See Rules Concerning Certification of the Electric Reliability Organization; and Procedures for the Establishment, Approval, and Enforcement of Electric Reliability Standards*, Order No. 672, FERC Stats. & Regs. ¶ 31,204, at P 262, 321-37, *order on reh'g*, Order No. 672-A, FERC Stats. & Regs. ¶ 31,212 (2006).

7 Unless otherwise indicated, capitalized terms shall have the meaning set forth in the *Glossary of Terms used in NERC Reliability Standards* ("NERC Glossary"), https://www.nerc.com/pa/Stand/Glossary%20of%20Terms/Glossary_of_Terms.pdf.

I. SUMMARY

The TPL-001 Reliability Standard is one of two Transmission Planning Reliability Standards that set forth Requirements for Planning Authorities and Transmission Planners to develop studies of their portions of the Bulk Electric System ("BES"). The purpose of proposed Reliability Standard TPL-001-5 is to "[e]stablish Transmission system planning performance requirements within the planning horizon to develop a [BES] that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies." The proposed standard would require each Planning Authority and Transmission Planner to perform an annual Planning Assessment[8] of its portion of the BES covering a number of System conditions and Contingencies described in the standard.

The proposed standard employs a risk-based approach to the study of Contingencies and the types of corrective action that are required if the entity's System cannot meet the standard's performance requirements. This risk-based approach is carried forward from currently effective Reliability Standard TPL-001-4. For the scenarios considered to be more commonplace ("planning events"), the planning entity must develop a Corrective Action Plan if it determines, through its studies, that its System would experience performance issues. For the scenarios considered to be less commonplace but which could result in potentially severe impacts such as Cascading ("extreme events"), the planning entity must conduct a comprehensive analysis to understand both the potential impacts on its system and the types of actions that could reduce or mitigate those impacts.

As discussed more fully in Section V, proposed Reliability Standard TPL-001-5 improves upon the currently effective standard by enhancing Requirements for the study of Protection

[8] "Planning Assessment" is defined in the NERC Glossary as a "documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies."

System single points of failure. In this context, a Protection System "single point of failure" refers to a non-redundant component of a Protection System that, if it failed, would affect Normal Clearing[9] of faults. NERC identified this issue as a reliability risk to be addressed based on its analysis of potential single points of failure on the BES using data obtained pursuant to a request for data under Section 1600 of the NERC Rules of Procedure. The proposed standard contains revisions to both the Table 1 planning event (Category P5) and extreme events (Stability 2.a-h) and the associated footnote 13 to provide for more comprehensive study of the potential impacts of Protection System single points of failure. Planning entities would be required to take action, consistent with currently effective TPL-001 Requirements, to address System performance issues identified as a result of these studies.

Additionally, the proposed standard addresses two Commission directives from Order No. 786.[10] First, the proposed standard provides for a more complete consideration of factors for selecting which known outages will be included in Near-Term Transmission Planning Horizon studies. The modifications reflected in proposed TPL-001-5 address the Commission's concern that the exclusion of known outages of less than six months in TPL-001-4 could result in outages of significant facilities not being studied.[11] Second, the proposed standard modifies Requirements for Stability analysis to require an entity to assess the impact of the possible unavailability of long lead time equipment, consistent with the entity's spare equipment strategy.[12]

---

9 "Normal Clearing" is defined in the NERC Glossary as "a protection system operates as designed and the fault is cleared in the time normally expected with proper functioning of the installed protection systems."

10 *See* Order No. 786 at PP 40, 89.

11 *See id.* at PP 41-45.

12 *See id.* at P 89 (directing NERC to consider such a revision upon the next review cycle of TPL-001-4).

Collectively, these revisions would help improve the quality and rigor of Planning Assessments, thereby contributing to a more reliable Bulk-Power System ("BPS"). The proposed standard also contains an update and a limited number of editorial revisions which improve the readability and organization of the standard.

As discussed more fully in Section V, NERC's proposed phased implementation plan strikes an appropriate balance between implementing the standard in a reasonably expeditious manner and allowing entities sufficient time to come into compliance. The proposed implementation plan recognizes the significant coordination and work that would need to be done to identify, study, and address potential Protection System single points of failure issues. Under the proposed plan, the proposed standard would become effective 36 months after regulatory approval, with additional time afforded to entities to come into compliance with provisions related to Protection System single point of failure analysis and related Corrective Action Plans.

For these reasons, and as discussed more fully herein, NERC respectfully requests that the Commission approve the proposed Reliability Standard and the related elements effective as proposed by NERC.

III. BACKGROUND

A. Regulatory Framework

By enacting the Energy Policy Act of 2005,[14] Congress entrusted the Commission with the duties of approving and enforcing rules to ensure the reliability of the BPS, and with the duties of certifying an ERO that would be charged with developing and enforcing mandatory Reliability Standards, subject to Commission approval. Section 215(b)(1)[15] of the FPA states that all users, owners, and operators of the BPS in the United States will be subject to Commission-approved Reliability Standards. Section 215(d)(5)[16] of the FPA authorizes the Commission to order the ERO to submit a new or modified Reliability Standard. Section 39.5(a)[17] of the Commission's regulations requires the ERO to file with the Commission for its approval each new Reliability Standard that the ERO proposes should become mandatory and enforceable in

---

[13] Persons to be included on the Commission's service list are identified by an asterisk. NERC respectfully requests a waiver of Rule 203 of the Commission's regulations, 18 C.F.R. § 385.203, to allow the inclusion of more than two persons on the service list in this proceeding.

[14] 16 U.S.C. § 824o.

[17] 18 C.F.R. § 39.5(a).

the United States, and each modification to a Reliability Standard that the ERO proposes should be made effective.

The Commission is vested with the regulatory responsibility to approve Reliability Standards that protect the reliability of the BPS and to ensure that Reliability Standards are just, reasonable, not unduly discriminatory or preferential, and in the public interest. Pursuant to Section 215(d)(2) of the FPA[18] and Section 39.5(c)[19] of the Commission's regulations, the Commission will give due weight to the technical expertise of the ERO with respect to the content of a Reliability Standard.

B. NERC Reliability Standards Development Procedure

The proposed Reliability Standard was developed in an open and fair manner and in accordance with the Commission-approved Reliability Standard development process.[20] NERC develops Reliability Standards in accordance with Section 300 (Reliability Standards Development) of its Rules of Procedure and the NERC Standard Processes Manual.[21]

In its order certifying NERC as the Commission's ERO, the Commission found that NERC's rules provide for reasonable notice and opportunity for public comment, due process, openness, and a balance of interests in developing Reliability Standards,[22] and thus satisfy certain of the criteria for approving Reliability Standards.[23] The development process is open to any person or entity with a legitimate interest in the reliability of the BPS. NERC considers the

comments of all stakeholders. Stakeholders must approve, and the NERC Board of Trustees must adopt, a Reliability Standard before NERC submits the Reliability Standard to the Commission for approval.

C. 2009 NERC Advisory, Order No. 754, and NERC Activities to Study Single Points of Failure on Protection Systems

On March 30, 2009, NERC issued an advisory report notifying the industry that failure of a single component of a Protection System caused three significant system disturbances in the previous five years.[24] Transmission Owners, Generation Owners, and Distribution Providers owning Protection Systems installed on the BES were advised to address single points of failure on their Protection Systems, when identified in routine system evaluations, to prevent N-1 transmission system contingencies from evolving into more severe or even extreme events. These entities were also advised to begin preparing an estimate of the resource commitment required to review, re-engineer, and develop a workable outage and construction schedule to address single points of failure.

On September 15, 2011, the Commission issued Order No. 754 approving an interpretation of TPL-002-0 Requirement R1.3.10.[25] In this Order, the Commission stated that it believed there is "an issue concerning the study of the non-operation of non-redundant primary protection systems; e.g., the study of a single point of failure on protection systems."[26] To address this concern, the Commission directed "Commission staff to meet with NERC and its appropriate subject matter experts to explore the reliability concern, including where it can best

25 *Interpretation of Transmission Planning Reliability Standard*, Order No. 754, 136 FERC ¶ 61,186 (2011). Reliability Standard TPL-002-0 was a predecessor to the currently-effective TPL-001-4 standard.

26 *Id.* at P 19.

be addressed, and identify any additional actions necessary to address the matter."[27] FERC also directed NERC to "to make an informational filing…explaining whether there is a further system protection issue that needs to be addressed and, if so, what forum and process should be used to address that issue and what priority it should be accorded relative to other reliability initiatives planned by NERC."[28]

In March 2012, NERC submitted an informational filing to the Commission summarizing the results of its early work to study the issue.[29] As described more fully in that filing, NERC staff, FERC technical staff, and industry stakeholders attended a technical conference on October 24–25, 2011, the purpose of which was to focus on the Commission's concern regarding assessment of Protection System failures. One outcome of the 2011 technical conference was that NERC would conduct a data collection effort to aid in assessing whether single points of failure in protection systems pose a reliability concern. To that end, the NERC Board of Trustees approved a request for data under Section 1600 of the NERC Rules of Procedure (the "Order No. 754 Data Request") on August 16, 2012.[30]

Over the next two years, NERC collected data from Transmission Planners. Using the collected data, two subcommittees of the NERC Planning Committee, the System Protection and Control Subcommittee ("SPCS") and the System Analysis and Modeling Subcommittee ("SAMS"), conducted an assessment of Protection System single points of failure. The findings

28 *Id*.

29 *Informational Filing of the North American Electric Reliability Corporation in Response to Order No. 754,* Docket No. RM10-6-000 (Mar. 15, 2012).

30 Request for Data or Information: Order No. 754 Single Point of Failure on Protection Systems (Aug. 16, 2012), http://www.nerc.com/pa/Stand/Pages/order_754.aspx. The process governing Requests for Data or Information is contained in Section 1600 of the NERC Rules of Procedure, http://www.nerc.com/AboutNERC/Pages/Rules-of-Procedure.aspx.

were presented in a September 2015 report titled *Order No. 754: Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request*.[31] In the report, the SPCS and SAMS found that single points of failure on Protection Systems did pose a reliability risk that warranted further action. The report concluded:

> Analysis of the data demonstrates the existence of a reliability risk associated with single points of failure in protection systems that warrants further action. The analysis shows that the risk from single point of failure is not an endemic problem and instances of single point of failure exposure are lower on higher voltage systems. However, the risk is sufficient to warrant further action. Risk-based assessment should be used to identify protection systems of concern (i.e., locations on the BES where there is a susceptibility to cascading if a protection system single point of failure exists). Not all failures adversely affect reliable operation of the bulk power system. The reliability risk varies based on which component of a protection system fails.[32]

The SPCS and the SAMS recommended, after considering a variety of alternatives to address this reliability concern, that NERC modify Reliability Standard TPL-001-4 through the NERC standards development process. The SPCS and the SAMS concluded that this approach best aligns with FERC Order No. 754 directives and maximizes reliability of Protection System performance. The report recommended that three-phase faults involving Protection System failures be assessed as an extreme event in the TPL-001 standard, as follows:

> Additional emphasis in planning studies should be placed on assessment of three-phase faults involving protection system single points of failure. This concern (the study of protection system single points of failure) is appropriately addressed as an extreme event in

---

[31] NERC SPCS/SAMS, *Order No. 754: Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request* (Sep. 2015) ("SPCS/SAMS Report"), https://www.nerc.com/comm/PC/System%20Protection%20and%20Control%20Subcommittee%20SPCS%2020/FERC%20Order%20754%20Final%20Report%20-%20SPCS-SAMS.pdf.

NERC submitted this report to the Commission on an informational basis on October 30, 2015 in Docket No. RM10-6-000. *See Informational Filing of NERC, Assessment of Protection System Single Points of Failure*, Docket No. RM10-6-000 (Oct. 30, 2015).

[32] SPCS/SAMS Report at 11.

> TPL-001-4 Part 4.5. From TPL-001-4, Part 4.5: If the analysis concludes there is cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.[33]

Following the issuance of this report, NERC initiated a standards development project to consider the specific recommendations from this report. Later, NERC expanded the scope of the project to address two Commission directives from Order No. 786 approving TPL-001-4, as discussed further below.

D. Order No. 786 Approving TPL-001-4

In Order No. 786, the Commission approved the currently effective version of the transmission system planning standard, TPL-001-4. In that Order, the Commission also issued several directives to NERC, including two relating to future standard modifications that are addressed in proposed Reliability Standard TPL-001-5.

First, the Commission expressed concern that the six month outage duration threshold in TPL-001-4 Requirement R1 could exclude planned maintenance outages of significant facilities from future planning assessments. The Commission found that "planned maintenance outages of less than six months in duration may result in relevant impacts during one or both of the seasonal off-peak periods," and that "[p]rudent transmission planning should consider maintenance outages at those load levels when planned outages are performed to allow for a single element to be taken out of service for maintenance without compromising the ability of the system to meet demand without loss of load."[34] The Commission further stated, "[a] properly planned transmission system should ensure the known, planned removal of facilities (i.e., generation,

[33] *Id. at* 11; *see also id.* at 9 (discussion of alternatives to address reliability risks).

[34] Order No. 786 at P 41.

transmission or protection system facilities) for maintenance purposes without the loss of non-consequential load or detrimental impacts to system reliability such as cascading, voltage instability or uncontrolled islanding."[35] The Commission directed NERC to modify the TPL-001 standard to address this concern.

Second, while stating that NERC had met the Commission's Order No. 693 directive to include a spare equipment strategy for steady state analysis in TPL-001-4, the Commission found that a spare equipment strategy for stability analysis was not addressed in the standard.[36] The Commission stated that it "believes that a similar spare equipment strategy for stability analysis should exist that requires studies to be performed for P0, P1 and P2 categories with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment."[37] Rather than direct a change at that time, however, the Commission directed NERC to consider the issue during the next review cycle of TPL-001-4.[38]

E. Project 2015-10 Single Points of Failure TPL-001

In October 2015, NERC initiated Project 2015-10 Single Points of Failure TPL-001 to address the Protection System single points of failure recommendations from the SPCS/SAMS report. Subsequently, the scope of the project was expanded to add consideration of the Commission's Order No. 786 directives and an update to a MOD standard reference in the TPL-001 standard. In developing the proposed standard, the standard drafting team considered the

---

35 *Id.*

36 Order No. 786 at P 88. In Order No. 693, the Commission directed NERC to modify TPL-001-0 "to require assessments of outages of critical long lead time equipment, consistent with the entity's spare equipment strategy." *See Mandatory Reliability Standards for the Bulk-Power System*, Order No. 693 at P 1768, FERC Stats. & Regs. ¶ 31,242 (2007) (Order No. 693), *order on reh'g*, Order No. 693-A, 120 FERC ¶ 61,053 (2007). This led to the development of TPL-001-4 Requirement R2, Part 2.1.5 addressing steady-state conditions to determine system response when critical equipment is unavailable for a prolonged period of time.

37 Order No. 786 at P 89.

38 *Id*.

discussion and recommendations of the SPCS/SAMS report on Protection System single points of failure. The standard drafting team also considered additional recommendations developed by the SAMS to address the two Order No. 786 directives,[39] feedback received throughout the standard development process, and its own experience and expertise in the subject matter area.[40]

The proposed standard and implementation plan were posted once for informal comment and three times for formal comment and ballot. The fifth draft of proposed Reliability Standard TPL-001-5 and the associated implementation plan were approved by the ballot body on October 22, 2018. The proposed standard received a 66.69 percent approval rating, with 86.39 percent quorum. The proposed implementation plan received a 72.44 percent approval rating, with 86.73 percent quorum. The NERC Board of Trustees adopted the proposed standard on November 7, 2018. A summary of the development history and the complete record of development is attached to this Petition as Exhibit G.

IV. JUSTIFICATION FOR APPROVAL

As discussed in Exhibit C and below, proposed Reliability Standard TPL-001-5 satisfies the Commission's criteria in Order No. 672 and is just, reasonable, not unduly discriminatory or preferential, and in the public interest. The purpose of the proposed standard is to "[e]stablish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliability over a broad spectrum of System conditions and following a wide range of probable Contingencies." As with the purpose

40 The standard drafting team roster for Project 2015-10 Single Points of Failure TPL-001 is attached to this Petition as Exhibit **H**.

statement, the applicability of the proposed standard (Planning Coordinators and Transmission Planners) remains unchanged from the currently effective standard.

Proposed Reliability Standard TPL-001-5 improves upon the currently effective version of the standard by revising the existing Table 1 planning and extreme events to require a more complete, risk-based analysis of how the failure of a non-redundant component of a Protection System would affect a planning entity's System. The proposed standard also improves upon the currently effective standard and addresses the Commission's standard modification directives from Order No. 786 by: (i) requiring a more comprehensive analysis of known outages in planning studies; and (ii) requiring entities to consider, in Stability analysis, the impacts of the possible unavailability of long lead time equipment, consistent with the entity's spare equipment strategy. Lastly, the proposed standard contains an update to a MOD standard reference and editorial revisions to improve organization.

The proposed standard revisions and the justification for each is provided below. The proposed revisions are shown in the TPL-001-5 redline attached to this Petition as Exhibit A.

A. Revisions to Address Studies of Single Points of Failure on Protection Systems

Proposed Reliability Standard TPL-001-5 contains a series of revisions to help ensure that planning entities are: (1) performing a more complete analysis of potential Protection System single point of failure issues on their Systems; and (2) taking appropriate action to address these concerns. The SPCS/SAMS report concluded that "the data demonstrates the existence of a reliability risk associated with single points of failure in protection systems that warrants further action" and that "risk-based assessment should be used to identify protection systems of concern (i.e., locations on the BES where there is a susceptibility to cascading if a protection system single point of failure exists).”[41] To address this concern, proposed Reliability Standard TPL-001-5 revises:

- the Table 1, Category P5 planning event, which would require the planning entity to study the impact on its System of Delayed Fault Clearing[42] due to the failure of a non-redundant component of a Protection System protecting the Faulted element to operate as designed;

- the Table 1, Stability Extreme Events 2.a-2.h, which would require the planning entity to study the impact on its System of a three-phase fault with failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing; and

- Table 1, footnote 13, which specifies the Protection System equipment to be considered as part of studying the Category P5 planning event and Stability Extreme Events 2.e-2.h.

Collectively, the proposed revisions help ensure that planning entities are performing a risk-based assessment of the potential impacts of Protection System single points of failure that could pose a risk to reliability. Each of these revisions in the proposed standard is discussed below, beginning with the revisions to Table 1, footnote 13 which specify the non-redundant Protection System components to be considered as part of planning studies.

1. Revisions to Table 1, Footnote 13

Proposed Reliability Standard TPL-001-5 employs a risk-based approach to the study of Protection System single points of failure. Accordingly, proposed Table 1, footnote 13 is intended to focus the planning entity’s consideration on those non-redundant components of a

[41] SPCS/SAMS Report at 11.

[42] “Delayed Fault Clearing” is defined in the NERC Glossary as “Fault clearing consistent with correct operation of a breaker failure protection system and its associated breakers, or of a backup protection system with an intentional time delay.”

Protection System that may, when they fail, lead to Delayed Fault Clearing when simulating the Category P5 planning event and Stability extreme events 2.e-h.

In proposed Reliability Standard TPL-001-5, the limited set of relay functions or types in Table 1, Footnote 13 is replaced with an expanded list of components to capture the Protection System single point of failure concern. Guided by the SPCS/SAMS report recommendations, the TPL-001-5 standard drafting team selected a list of components to account for: (1) those failed non-redundant components of a Protection System that may impact one or more Protection Systems; (2) the duration that faults remain energized until Delayed Fault Clearing; and (3) the additional system equipment removed from service following fault clearing depending on the specific failed non-redundant component of a Protection System.[43]

Footnote 13 is revised to list four specific types of non-redundant Protection System components, as follows:

> ~~13. Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).~~
>
> 13. For purposes of this standard, non-redundant components of a Protection System to consider are as follows:
>
>   a. A single protective relay which responds to electrical quantities, without an alternative (which may or may not respond to electrical quantities) that provides comparable Normal Clearing times;
>
>   b. A single communications system associated with protective functions, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing (an exception is a single communications system that is both monitored and reported at a Control Center);
>
>   c. A single station dc supply associated with protective functions required for Normal Clearing (an exception

[43] See Technical Rationale at 4-5. Additional information regarding the selection of each particular component is available in the Technical Rationale on pages 5-10.

is a single station dc supply that is both monitored and reported at a Control Center for both low voltage and open circuit);

d. A single control circuitry (including auxiliary relays and lockout relays) associated with protective functions, from the dc supply through and including the trip coil(s) of the circuit breakers or other interrupting devices, required for Normal Clearing (the trip coil may be excluded if it is both monitored and reported at a Control Center).

The revised Footnote 13 does not include all Protection System components in the list of potential non-redundant components to consider. The SPCS/SAMS report described failure of voltage or current sensing devices as having a lower level of risk of failure to trip.[44] The reliability risk associated with the failure of these components is lower than the risk posed by the failure of a Protection System component that is needed to clear a fault. Therefore, voltage or current sensing devices are not included in the revised footnote 13. Similarly, control circuitry whose failure does not prevent Normal Clearing of a fault, such as reclosing circuitry and reclosing relays, is not considered under the revised footnote 13.[45]

An explanation for each of the types of devices to be included in Protection System single point of failure studies under revised footnote 13a.-d is provided below.

a) Footnote 13.a – Protective Relays

Footnote 13.a includes among the components to consider "a single protective relay which responds to electrical quantities, without an alternative (which may or may not respond to electrical quantities) that provides comparable Normal Clearing times." Other Requirements address simulation of Protection System action.[46] Footnote 13.a therefore limits the potential

---

44 *See* Technical Rationale at 5; *see also* SPCS/SAMS Report at 7.

45 *See* Technical Rationale at 5.

46 *See* TPL-001-5 Requirement R3 Part 3.3.1 and Requirement R4 Part 4.3.1.

single points of failure to study to those single protective relays which respond to electrical quantities and are used for primary protection resulting in Normal Clearing. A single point of failure in such a relay may result in the primary Protection System failing to operate properly, leading to Delayed Fault Clearing performed by backup protective relays and/or overlapping zonal protection.[47] For footnote 13.a, an "alternative that provides comparable Normal Clearing times" refers to a relay that results in fault clearing within the expected Normal Clearing time period and isolates the fault by tripping similar System Elements than if the single protective relay that is simulated to fail were to function properly. By noting that the alternative may or may not respond to electrical quantities, Footnote 13.a accounts for those Protection System designs in which non-redundant single protective relays which respond to electrical quantities may be redundant to protective relays that do not respond to electrical quantities.[48]

b) Footnote 13.b – Communications Systems

Footnote 13.b includes among the Protection System components to consider a "a single communications system associated with protective functions, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing (an exception is a single communications system that is both monitored and reported at a Control Center)." Given the increasing importance of communication-aided Protection Systems, the proper operation of the communication system must be considered when considering potential Protection System components to study for single points of failure concerns. A communication-aided Protection System that may experience a single point of failure, causing it to operate improperly or not at all, must be considered among non-redundant components.

[47] Footnote 13.a does not include backup protective relays given that a single point of failure in a single protective relay used for backup protection will not affect primary protection resulting in Normal Clearing.

[48] For an example of such a design, see the Technical Rationale at 5-7.

Footnote 13 provides that certain non-redundant components that are both monitored and reported at a Control Center would not need to be considered as part of planning studies. This includes the communications systems identified in footnote 13.b. The standard drafting team considered that the monitoring and reporting of a non-redundant component to a centralized location (i.e., the Control Center) would facilitate prompt identification and correction of abnormal conditions to minimize the exposure to and consequence of the failed component. Therefore, it concluded that such monitored and reported components exhibited a lower risk, on par with being redundant, than a non-redundant component that reported to a remote location or one whose failure might go undetected for some time.[49]

c) Footnote 13.c – Station DC Supply

Footnote 13.c includes among the Protection System components to consider "a single station dc supply associated with protective functions required for Normal Clearing (an exception is a single station dc supply that is both monitored and reported at a Control Center for both low voltage and open circuit)." Failure of a single station Protection System DC supply is a significant point of failure as it will prevent the operation of all local protection, including back-up protection. Similar to footnote 13.b, monitoring and reporting the status of the DC supply to a centralized location can be considered a sufficient alternative to physical redundancy if the result is prompt notification and remediation which minimizes the exposure to and consequence of DC supply failure.

d) Footnote 13.d – Control Circuitry

Lastly, footnote 13.d would require consideration of "a single control circuitry (including auxiliary relays and lockout relays) associated with protective functions, from the dc supply

[49] Technical Rationale at 5.

through and including the trip coil(s) of the circuit breakers or other interrupting devices, required for Normal Clearing (the trip coil may be excluded if it is both monitored and reported at a Control Center).” Failure of a Protection System single control circuitry is a significant point of failure as it will prevent proper tripping and, depending upon its design and mode of failure, may also prevent the initiation of breaker failure protection.[50] Further, most, if not all, constituent parts of the control circuitry are generally unmonitored, may fail, and may remain undetected until periodic testing is conducted. This is particularly significant for non-redundant auxiliary relays or lockout relays within the control circuitry because they may be used for multiple functions, such as multiplexing trip signals for differential or breaker failure initiation. Single control circuitry should be considered a non-redundant component of a Protection System given that Delayed Fault Clearing, including significantly delayed remote end or backup clearing, is expected when the non-redundant auxiliary or lockout relay device within the single control circuitry fails.

The single control circuitry is demarcated from the DC supply through and including the trip coil(s) for the purpose of including all devices in the control circuitry which, if failed, may prevent proper Protection System action leading to Delayed Fault Clearing. Trip coils are commonly employed in pairs for the purpose of incorporating redundancy to actuate the tripping of a circuit breaker or other interrupting device. When a single trip coil is employed, monitoring and reporting the status of the single trip coil to the Control Center can be considered as a sufficient alternative to its physical redundancy given that prompt notification and remediation is expected, which minimizes the risk the trip coil failure. However, all constituent parts of the

[50] Breaker failure is addressed by the Table 1, Category P4 planning event.

single control circuit (including wires) should be included when considering whether the single control circuit may be a non-redundant component of a Protection System.

2. Revisions to the Table 1, Category P5 Planning Event

The Category P5 event in Table 1 of proposed Reliability Standard TPL-001-5 would require the planning entity to simulate a Contingency where a single line-to-ground fault occurs and Delayed Fault Clearing results due to the failure of a non-redundant component of a Protection System protecting the Faulted element to operate as designed. Stated differently, the Protection System does not operate as designed to clear the single line-to-ground fault in the time normally expected with proper functioning of the Protection System due to a single point of failure. When a Protection System does not operate as designed or fails to isolate faulted equipment within the time normally expected with its proper functioning, backup protection capabilities must act to clear the fault. Such backup systems are designed with intentional time delays before fault clearing. Additionally, the operation of these backup systems could result in significant differences in final System configuration. For example, more System Elements may be removed from service when the backup Protection System operates than may be expected during primary Protection System operation.

Revisions are proposed to the Category P5 event to be consistent with the revisions to footnote 13, replacing the word “relay” with the more inclusive phrase “component of a Protection System”, as follows:

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P5 Multiple Contingency *(Fault plus ~~relay~~non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant ~~relay[13]~~component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes

Consistent with currently effective Reliability Standard TPL-001-4, the entity would be required to develop a Corrective Action Plan in the event it determines that its System would be unable to meet the performance requirements of Table 1 for the Category P5 event. Corrective action requirements for the revised Protection System single point of failure studies are discussed in Section IV.A.4, below.

3. Revisions to Table 1, Extreme Events, Stability Column Events

Consistent with the recommendations of the SPCS/SAMS report, proposed Reliability Standard TPL-001-5 revises the Table 1 Extreme Events to place additional emphasis on assessment of three-phase faults involving single points of failure on a Protection System. In proposed Reliability Standard TPL-001-5, the extreme events in the Stability column of Table 1 is revised so that four distinct items, 2.e-2.h, would address study of Protection System single points of failure in combination with three-phase faults, as follows:

Table 1, Steady State & Stability Performance Extreme Events

Stability

***

2. Local or wide area events affecting the Transmission System such as:

a. 3Ø fault on generator with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.

b. 3Ø fault on Transmission circuit with stuck breaker[10] ~~or a relay failure~~~~[13]~~ resulting in Delayed Fault Clearing.

c. 3Ø fault on transformer with stuck breaker[10] ~~or a relay failure~~~~[13]~~ resulting in Delayed Fault Clearing.

d. 3Ø fault on bus section with stuck breaker[10] ~~or a relay failure~~~~[13]~~ resulting in Delayed Fault Clearing.

e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

~~e.~~i. 3Ø internal breaker fault.

~~f.~~j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

As demonstrated above, Table 1, Extreme Events, Stability column, items 2.a. through 2.d are revised to strike the term “relay failure.” Items 2.e through 2.h are added to address specifically the study of a three-phase fault on a generator, Transmission circuit, transformer, or bus section in combination with a failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing. Footnote 13, discussed above, identifies the specific non-redundant components of a Protection System that should be considered as part of these extreme event studies.

As discussed in the following section, proposed Reliability Standard TPL-001-5 carries forward requirements from TPL-001-4 relating to the action the planning entity must take in the event its studies indicate System performance issues for this event.

4. Corrective Action Requirements for the Revised Table 1 Category P5 and Stability Extreme Events Items 2.e-2.h Studies

The proposed TPL-001-5 Reliability Standard, like the currently effective TPL-001-4 standard, takes a risk-based approach to System planning studies. Generally, the standard contains more stringent corrective action requirements for the more commonplace scenarios, and less stringent corrective action requirements for the rarest, but potentially most severe, scenarios. This general framework is based on widely-accepted principles of cost-effective, risk-based planning. As the Commission stated in a prior proceeding, "The Commission agrees that [the extreme event Transmission Planning] Reliability Standard should not require improvements for low probability events that cannot be justified."[51] The planning entity should, however, be required to fully understand the potential impacts such events could have on its System and the steps that could be taken to address those impacts.[52] The planning entity would then use this information to make an informed decision on the best way to plan its System for these rare scenarios. This decision should take into account all relevant considerations. By way of example, those considerations could include the entity's planning priorities, the probability of the event, and the expected impacts of the event. These considerations could also include the interests of its customers and the entity's ability to obtain cost recovery.

Proposed Reliability Standard TPL-001-5 carries forward this risk-based approach to the study of Protection System single points of failure. As discussed in the previous sections, TPL-001-5 replaces "relays" as the equipment to be studied in the Table 1, Category P5 planning

---

[51] *See* Notice of Proposed Rulemaking, *Mandatory Reliability Standards for the Bulk-Power System*, 117 FERC ¶ 61,084 (Oct. 20, 2006) at P 1112 (proposing to approve Reliability Standard TPL-004-0 – System Performance Following Extreme BES Events, which is a predecessor to the currently effective TPL-001-4 standard).

[52] *See id.* and Order No. 693 at P 1836 (approving TPL-004-0 and directing NERC to modify the standard to require, among other things, "the identification of options for reducing the probability or impacts of extreme events that cause cascading.")

event and Stability extreme events items 2.e-2.h with a broader list of potentially problematic non-redundant Protection System components. The approach to mitigation for these events remains unchanged from currently effective TPL-001-4.

The single line-to-ground fault scenario described in the revised Category P5 planning event is considered to be the more commonplace scenario involving Protection System single points of failure; therefore, if the planning entity determines that its System is unable to meet the standard's performance requirements, it must develop a Corrective Action Plan to address the deficiencies. Requirement R2.7 in proposed Reliability Standard TPL-001-5 addresses Corrective Action Plan requirements and remains substantively unchanged from the currently effective standard. Such Corrective Action Plans for the Category P5 planning event may include adding redundant components; however, this is only one of many alternatives for corrective actions that planning entities may consider to achieve required System performance.

By contrast, the three phase fault scenario described in the revised Table 1, Extreme Events, Stability column items 2.e-h is considered to be the much rarer occurrence, as discussed further below. Like the other extreme events in the proposed standard, this scenario, while rare, could result in more significant impacts to an entity's System. During the development of the proposed standard, the standard drafting team considered several alternative approaches to the study of Protection System single points of failure with three-phase faults, particularly the type of mitigation action that should be required by the standard. Taking into account all relevant considerations, including industry feedback and the recommendations of the SPCS/SAMS report, the TPL-001-5 drafting team determined that the most appropriate and cost effective approach would be to carry forward the approach of currently effective TPL-001-4. Under this approach, if an entity determines that its System will experience Cascading[53] as a result of a three-phase fault scenario, "an evaluation of possible actions designed to reduce the likelihood or mitigate the consequence(s) of the event shall be conducted." In proposed Reliability Standard TPL-001-5, this Requirement is carried forward in Requirement R4 Part 4.2.[54] The ERO would continue to audit compliance with this analysis provision similarly to how it is audited under the currently effective standard, taking into account the expanded list of Protection System components considered in the study.

The corrective action requirements for the revised single line-to-ground fault and three phase fault scenarios fit within the risk-based framework of the TPL-001 standard. Data collected by NERC since 2011 provides further support that this framework remains appropriate for Protection System single points of failure studies. Like all of the "extreme event" scenarios in this framework, the impacts of a Protection System single point of failure in combination with a three phase fault could be severe in some cases, but are very unlikely. A historical analysis of NERC's data on Protection System misoperations indicates that the expected likelihood of such an event occurring and resulting in the most severe impacts would be small. NERC recently completed a review of over 12,000 Protection System misoperations in its Misoperation Information Data Analysis System ("MIDAS") database reported since 2011.[55] Of the over

---

53 Cascading is defined in the NERC Glossary as: "The uncontrolled successive loss of System Elements triggered by an incident at any location. Cascading results in widespread electric service interruption that cannot be restrained from sequentially spreading beyond an area predetermined by studies."

54 This provision is unchanged from currently-effective TPL-001-4, except that it is moved from Requirement R4 Part 4.5 to Part 4.2 in proposed TPL-001-5 for editorial reasons. Similarly, the provision applicable to steady state extreme events analysis is moved from Requirement R3 Part 3.5 to Part 3.2.

55 The ERO began to collect misoperations data in a common format beginning in 2011. Applicable entities are currently required to report information on Protection System misoperations to NERC pursuant to a request for data or information under Section 1600 of the NERC Rules of Procedure approved by the NERC Board of Trustees on August 14, 2014. Previously, the PRC-004 standard contained requirements for misoperation reporting.

12,000 Protection System misoperations in MIDAS, 28 involved three-phase faults. Of that number, only 10 involved breakers that failed to operate (the remaining 18 involved breakers that were slow to operate). Failure to operate potentially indicates instances of a Protection System single point of failure. While the potential for severe impacts from such events remains, none of the 10 failure to trip scenarios reported since 2011 resulted in events that reached the threshold for reporting to NERC under Reliability Standard EOP-004.[56]

For these reasons, it remains appropriate to carry forward the risk-based mitigation approach in currently effective Reliability Standard TPL-001-4 to the revised Protection System single points of failure planning studies in proposed Reliability Standard TPL-001-5.

B. Revisions to Address Order No. 786 Directives

In addition to addressing reliability issues involving single points of failure on Protection Systems, proposed Reliability Standard TPL-001-5 revises the TPL-001 standard to address two Commission directives from Order No. 786. Under the first directive, the Commission directed NERC to modify TPL-001-4 to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments.[57] Under the second directive, the Commission directed NERC to consider whether TPL-001-4 should contain a spare equipment strategy for Stability analysis, similar to that for steady state analysis.[58] For steady state analysis, TPL-001-4 Requirement R2 Part 2.1.5 requires studies to be performed for P0, P1, and P2 categories with the conditions that the system is expected to

[56] The EOP-004 Reliability Standard specifies Requirements for entities to report disturbances and events that have the potential to impact the reliability of the BPS.

[57] Order No 786 at P 40.

[58] *Id.* at P 89.

experience during the possible unavailability of the long lead-time equipment. A discussion of the revisions in proposed TPL-001-5 to address these directives is provided below.

1. Study of Known Planned Outages

In proposed Reliability Standard TPL-001-5, NERC made several revisions to address the Commission's concern in Order No. 786 that the six-month threshold in TPL-001-4 Requirement R1 Part 1.1.2 could exclude planned maintenance outages of significant facilities from future planning assessments.[59] The proposed revisions are intended to complement Reliability Standard IRO-017-1, which requires: (1) each Reliability Coordinator to maintain an outage coordination process within its Reliability Coordinator Area; and (2) each Planning Coordinator and Transmission Planner to provide its Planning Assessment to impacted Reliability Coordinators and to jointly develop solutions with its Reliability Coordinator(s) for identified issues or conflicts with planned outages.

The proposed revisions are intended to strengthen the collaboration and consultation between the Reliability Coordinator and the Transmission Planner or Planning Coordinator at the outset of determining the known outages that should be assessed in the Near-Term Transmission Planning Horizon. In developing a comprehensive approach to the study of known outages in Planning Assessments, and one that is flexible enough to accommodate the various outage coordination processes in use across the North America, the TPL-001-5 standard drafting team considered the Commission's guidance in Order No. 786, the recommendations of the NERC SAMS, feedback received during the standard development process, as well its own experience and subject matter expertise.

---

[59] *Id.* at P 40.

In proposed TPL-001-5, the provision relating to the assessment of known outages (Requirement R1 Part 1.1.2) is struck from Requirement R1 and new provisions are added under Requirement R2, Parts 2.1 and 2.4. These new provisions specify how analyses shall be assessed and supported by studies. The relevant revisions to Requirement R2 are shown below:

> **R2.** Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*
>
> **2.1.** For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:
>
> **2.1.1.** System peak Load for either Year One or year two, and for year five.
>
> **2.1.2.** System Off-Peak Load for one of the five years.
>
> ~~**2.1.3.** P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled~~.
>
> *******
>
> <u>**2.1.4.** When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P0 and P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum known outages expected to produce more severe System impacts on the</u>

Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1.

***

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part 2.6. The following studies are required:

***

2.4.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum, those known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1.

***

In proposed Reliability Standard TPL-001-5, the six month outage threshold is removed. Planning entities would instead select known outages for study based on a documented procedure or rationale that takes into account relevant factors, but does not exclude known planned outages based solely on the outage duration. The change to where the assessment of known outages is specified in the TPL-001-5 requirements better aligns the approach necessary for the planning entities to execute their annual Planning Assessments. Further, the proposed Requirement language recognizes the various means that Planning Coordinators and Transmission Planners currently employ to consider the maintenance outages that could potentially be of concern.

Under proposed Requirement R2 Parts 2.1.4 and 2.4.4., each Planning Coordinator and Transmission Planner must have either a documented outage coordination procedure or technical rationale to select which known outages shall be assessed as part of the steady state (Requirement R2, Part 2.1.4) and Stability (Requirement R2, Part R2.4.4) analysis. The documented outage coordination procedure would include consultation with the affected Reliability Coordinator, consultation with Transmission and/or Generator Owner(s) affected by the known outage, or application of documented outage coordination processes. The technical rationale would include the well-reasoned technical bases for making the determination of which known outages to assess.

Consistent with the intention of Order No. 786, the proposed provisions specify that an entity shall not exclude known outages to be modeled based solely on the outage duration. However, the presence of other accompanying factors, which in conjunction with outage duration, may form a reasonable basis for supporting that the known outage need not be assessed in the Near-Term Transmission Planning Horizon.

Under the proposed standard, an entity would be required to include, at a minimum, those known outages expected to cause more severe System impacts, such as those that may result in Non-Consequential Load Loss for the Table 1 Category P1 event. The Planning Coordinator and Transmission Planner would have flexibility to use the appropriate means to assess which known outages are expected to be significant, and to exclude from the assessment those outages which the Planning Coordinator and Transmission Planner do not expect to be problematic. When selecting those known outages for study, consideration must be paid to the System conditions, such as On-Peak or Off-Peak, that are expected during the period when the known outage is planned. The proposed standard provides that past or current studies may support the selection of one or more known outages, if the past or current study or studies has comparable post-Contingency System conditions and configuration. For example, in many cases the Category P3 and P6 event study could result in the same System state as the Category P1 event with the known outage. Such analysis, therefore, may be useful in helping to select which known outages to study.

2. Spare Equipment Strategy for Stability Analysis

NERC also proposes revisions to address the Commission's Order No. 786 directive to consider adding provisions for spare equipment strategy as part of Stability analysis. In Order No. 786, the Commission noted that TPL-001-4 Requirement R2 Part 2.1.5 requires that steady state studies be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment. The Commission stated that it believed that "a similar spare equipment strategy for stability analysis should exist that requires studies to be performed for P0, P1 and P2 categories with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment." The Commission directed NERC to consider the issue upon the next review cycle of TPL-001-4.[60]

[60] Order No. 786 at P 89.

Consistent with the Commission's Order No. 786 guidance, the standard drafting team revised the standard to add a similar requirement for Stability analysis, as follows:

> **2.4.** For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:
>
> ***
>
> **2.4.5.** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

The addition of Requirement R2, Part 2.4.5, which includes similar language to that used for the steady-state analysis under Requirement R2, Part 2.1.5,[61] clarifies that the outage of long lead time Elements has an equally important impact from a Stability standpoint as it does from a steady-state standpoint and should be assessed commensurate with an entity's spare equipment strategy. While the language in the two provisions is similar, there are two important differences.

First, the Category P0 event is not included because it is implied in the study. The nature of Stability analysis is to observe the System dynamic response during and after a disturbance. The Category P0 event conditions represent the undisturbed, initial, "normal" state of the System. Given that initial System conditions for each long-lead time Element that is removed from service are identical between steady state and Stability analyses, the Stability analysis of

61 Corresponding editorial changes are proposed in Requirement R2, Part 2.1.5, as shown in Exhibit A.

the P0 event is implicitly assessed when conducting the steady state analysis of the P0 event. Similarly, the prerequisite for conducting the Category P1 and P2 event Stability analysis is a System model that incorporates and is initialized as the undisturbed (P0) state of the System. Therefore, Category P0 is redundant and is appropriately omitted from Requirement R2 Part 2.4.5.

Second, proposed Reliability Standard TPL-001-5 Requirement R2 Part 2.4.5 provides that "an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES." The dynamic response of the System and its ability to meet performance requirements are expected to be more stressed for certain Category P1 and P2 category events, topologically close to where the long-lead time Element is removed from service. Consistent with Requirement R3 Part 3.4, those Category P1 and P2 events expected to produce more severe System impacts are selected for Stability analysis. Additionally, prior testing and knowledge of system performance can help to limit Stability testing to the relevant limiting events.

C. Other Revisions

Proposed Reliability Standard TPL-001-5 also contains several other revisions not specifically highlighted above. First, the reference to the MOD-010 and MOD-012 standard in Requirement R1 is replaced with a reference to the MOD-032 standard, which now contains the relevant Requirements.[62] Second, references to "Special Protection System" have been replaced with "Remedial Action Scheme," consistent with previously-approved revisions to those defined

[62] The Commission approved Reliability Standard MOD-032-1 and the retirement of Reliability Standards MOD-010-0 and MOD-012-0 in 2014. *See N. Am. Elec. Reliability Corp.*, Docket No. RD14-5-000 (May 1, 2014) (delegated letter order).

terms.[63] Lastly, a series of moves and formatting changes have been made to conform the standard to the current NERC standard template. These proposed changes are shown in redline in Exhibit A.

D. Enforceability of the Proposed Reliability Standard

The proposed Reliability Standard contains Violation Risk Factors ("VRFs") and Violation Severity Levels ("VSLs") for each of the standard's Requirements. The VRFs and VSLs provide guidance on the way that NERC will enforce the Requirements of the proposed Reliability Standard. The VRFs and VSLs are substantively unchanged from currently effective Reliability Standard TPL-001-4 and continue to comport with NERC and Commission guidelines related to their assignment.

In addition, the proposed Reliability Standard also includes Measures that support the Requirements by clearly identifying what is required and how the Requirement will be enforced. The Measures, which are unchanged from currently-enforceable Reliability Standard TPL-001-4, helps ensure that the Requirements will be enforced in a clear, consistent, and non-preferential manner and without prejudice to any party.

V. EFFECTIVE DATE

NERC respectfully requests that the Commission approve the proposed implementation plan attached to this Petition as Exhibit B. Under the proposed implementation plan, Reliability Standard TPL-001-5 would become effective on the first day of the first calendar quarter that is

---

[63] In 2016, the Commission approved the revised definition of Remedial Action Scheme. *See Revisions to Emergency Operations Reliability Standards; Revisions to Undervoltage Load Shedding Reliability Standards; Revisions to the Definition of "Remedial Action Scheme" and Related Reliability Standards*, Order No. 818, 153 FERC ¶ 61,228, at PP 24, 31 (2015). In 2016, the Commission approved the revised definition of Special Protection System, to have the same meaning of Remedial Action Scheme. *See N. Am. Elec. Reliability Corp.*, Docket No. RD16-5-000 (June 23, 2016) (delegated letter order).

36 months after regulatory approval. Reliability Standard TPL-001-4 would be retired immediately prior to the effective date of TPL-001-5.

Under the TPL-001-5 implementation plan, entities have additional time to come into compliance with certain Requirements related to the study of single points of failure on Protection Systems. Specifically, planning entities would have an additional 24 months after the effective date of the standard to develop Corrective Action Plans under Requirement R2, Part 2.7 for the Table 1 Category P5 planning event involving the non-redundant components of a Protection System specified in Footnote 13 items a, b, c, and d. Further, entities shall have an additional 72 months after the effective date of the standard to comply with the underlined part of Requirement R2, Part 2.7 that states: "Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments <u>but the planned System shall continue to meet the performance requirements in Table 1.</u>"

As explained in Exhibit B, the proposed implementation plan recognizes that Planning Coordinators and Transmission Planners will need time to develop a procedure or technical rationale for selecting known outages for study and for completing those planning studies. Further, the implementation plan recognizes that Planning Coordinators and Transmission Planners would need to engage in a substantial amount of work and coordination with asset owners and protection engineers to perform the new Protection System single points of failure studies and to coordinate on appropriate Corrective Action Plan measures and timetables to address System performance issues. This is especially true in cases where Corrective Action Plans may call for adding redundant Protection System components.

The proposed implementation plan recognizes the importance of ensuring that the potential risks of known outages and Protection System single points of failure are being addressed in planning studies. Based upon the considerations described above, the proposed implementation plan also provides a reasonable period of time for entities to come into compliance with the proposed standard. For these reasons, NERC respectfully requests that the Commission approve the proposed implementation plan.

VI. CONCLUSION

For the reasons set forth above, NERC respectfully requests that the Commission approve:

- proposed Reliability Standard TPL-001-5 and associated elements included in **Exhibit A**;
- the implementation plan included in **Exhibit B**; and
- the retirement of currently effective Reliability Standard TPL-001-4.

Respectfully submitted,

/s/ Lauren A. Perotti

Counsel for the North American Electric Reliability Corporation

December 7, 2018

Exhibit A

Proposed Reliability Standard TPL-001-5

TPL-001-5 Clean Version

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**
2. **Number:** **TPL-001-5**
3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.
4. **Applicability:**

   4.1. Functional Entity

   - Planning Coordinator.
   - Transmission Planner.

5. **Effective Date: See Implementation Plan.**

B. Requirements and Measures

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities.

1.1.2. New planned Facilities and changes to existing Facilities.

1.1.3. Real and reactive Load forecasts.

1.1.4. Known commitments for Firm Transmission Service and Interchange.

1.1.5. Resources (supply or demand side) required for Load.

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within its respective area, using data consistent with MOD-032, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short

circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response :

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P0 and P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

2.4.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum, those known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments, but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or Remedial Action Schemes.
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an

evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

3.3. Contingency analyses for Requirement R3, Parts 3.1 and 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a Remedial Action Scheme is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event (s) shall be conducted.

4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall :

4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

4.3.1.1. Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2. Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3. Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power

system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for

performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

C. Compliance

1. **Compliance Monitoring Process**

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data identified in Measures M1 through M8 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Compliance Monitoring Period and Reset Timeframe:

Not applicable.

1.5. Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checks
- Compliance Violation Investigations
- Self-Report
- Complaints

1.6. Additional Compliance Information

None.

0.1	October 29, 2008	BOT adopted errata changes; updated version number to “0.1”	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote ‘b’ pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
		TPL-001-3 was created after the Board of Trustees approved the revised footnote 'b' in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	November 7, 2018	Adopted by the NERC Board of Trustees.	Revised to address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability: a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. d. Simulate Normal Clearing unless otherwise specified. e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only**: f. Applicable Facility Ratings shall not be exceeded. g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. h. Planning event P0 is applicable to steady state only. i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only:** j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P0 No Contingency	Normal System	None	N/A	EHV, HV	No	No
P1 Single Contingency	Normal System	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single Pole of a DC line	SLG			
P2 Single Contingency	Normal System	1. Opening of a line section w/o a fault [7]	N/A	EHV, HV	No[9]	No[12]
		2. Bus Section Fault	SLG	EHV	No[9]	No
				HV	Yes	Yes
		3. Internal Breaker Fault[8] (non-Bus-tie Breaker)	SLG	EHV	No[9]	No
				HV	Yes	Yes
		4. Internal Breaker Fault (Bus-tie Breaker)[8]	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P3 Multiple Contingency	Loss of generator unit followed by System adjustments[9]	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single pole of a DC line	SLG			
P4 Multiple Contingency *(Fault plus stuck breaker[10])*	Normal System	Loss of multiple elements caused by a stuck breaker[10](non-Bus-tie Breaker) attempting to clear a Fault on one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
		6. Loss of multiple elements caused by a stuck breaker[10] (Bus-tie Breaker) attempting to clear a Fault on the associated bus	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P5 Multiple Contingency *(Fault plus non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
P6 Multiple Contingency *(Two overlapping singles)*	Loss of one of the following followed by System adjustments.[9] 1. Transmission Circuit 2. Transformer [5] 3. Shunt Device[6] 4. Single pole of a DC line	Loss of one of the following: 1. Transmission Circuit 2. Transformer[5] 3. Shunt Device[6]	3Ø	EHV, HV	Yes	Yes
		4. Single pole of a DC line	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P7 Multiple Contingency *(Common Structure)*	Normal System	The loss of: 1. Any two adjacent (vertically or horizontally) circuits on common structure [11] 2. Loss of a bipolar DC line	SLG	EHV, HV	Yes	Yes

<table>
<tr><th colspan="2">Table 1 – Steady State & Stability Performance Extreme Events</th></tr>
<tr><td colspan="2">Steady State & Stability
For all extreme events evaluated:
a. Simulate the removal of all elements that Protection Systems and automatic controls are expected to disconnect for each Contingency.
b. Simulate Normal Clearing unless otherwise specified.</td></tr>
<tr><td>Steady State
1. Loss of a single generator, Transmission Circuit, single pole of a DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, single pole of a different DC Line, shunt device, or transformer forced out of service prior to System adjustments.
2. Local area events affecting the Transmission System such as:
a. Loss of a tower line with three or more circuits.[11]
b. Loss of all Transmission lines on a common Right-of-Way[11].
c. Loss of a switching station or substation (loss of one voltage level plus transformers).
d. Loss of all generating units at a generating station.
e. Loss of a large Load or major Load center.
3. Wide area events affecting the Transmission System based on System topology such as:
a. Loss of two generating stations resulting from conditions such as:
i. Loss of a large gas pipeline into a region or multiple regions that have significant gas-fired generation.</td>
<td>Stability
1. With an initial condition of a single generator, Transmission circuit, single pole of a DC line, shunt device, or transformer forced out of service, apply a 3Ø fault on another single generator, Transmission circuit, single pole of a different DC line, shunt device, or transformer prior to System adjustments.
2. Local or wide area events affecting the Transmission System such as:
a. 3Ø fault on generator with stuck breaker[10] resulting in Delayed Fault Clearing.
b. 3Ø fault on Transmission circuit with stuck breaker[10] resulting in Delayed Fault Clearing.
c. 3Ø fault on transformer with stuck breaker[10] resulting in Delayed Fault Clearing.
d. 3Ø fault on bus section with stuck breaker[10] resulting in Delayed Fault Clearing.
e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.</td></tr>
</table>

ii. Loss of the use of a large body of water as the cooling source for generation. iii. Wildfires. iv. Severe weather, e.g., hurricanes, tornadoes, etc. v. A successful cyber attack. vi. Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. i. 3Ø internal breaker fault. j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss.
2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria.
3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss.
4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service.
5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers.
6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground.
7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point.
8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker.
9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered.

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing. 11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less. 12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction. 13. For purposes of this standard, non-redundant components of a Protection System to consider are as follows: a. A single protective relay which responds to electrical quantities, without an alternative (which may or may not respond to electrical quantities) that provides comparable Normal Clearing times; b. A single communications system associated with protective functions, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing (an exception is a single communications system that is both monitored and reported at a Control Center); c. A single station dc supply associated with protective functions required for Normal Clearing (an exception is a single station dc supply that is both monitored and reported at a Control Center for both low voltage and open circuit); d. A single control circuitry (including auxiliary relays and lockout relays) associated with protective functions, from the dc supply through and including the trip coil(s) of the circuit breakers or other interrupting devices, required for Normal Clearing (the trip coil may be excluded if it is both monitored and reported at a Control Center).

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. .The process must include the following:

1. Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues
2. Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:
    a. Date, time, and location for the meeting
    b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
    c. Provisions for a stakeholder comment period
3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
    a. System Load level and estimated annual hours of exposure at or above that Load level

  b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency

2. Amount of Non-Consequential Load Loss with:
   a. The estimated number and type of customers affected
   b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community
3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance
4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance
5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12
6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12
7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12
8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

1. The voltage level of the Contingency is greater than 300 kV
   a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or
   b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)

2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

TPL-001-5 Redline Version

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**

2. **Number:** **TPL-001-~~4~~5**

3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

4. **Applicability:**

   4.1. Functional Entity

   - Planning Coordinator.
   - Transmission Planner.

5. **Effective Date:** **See Implementation Plan.**~~Requirements R1 and R7 as well as the definitions shall become effective on the first day of the first calendar quarter, 12 months after applicable regulatory approval. In those jurisdictions where regulatory approval is not required, Requirements R1 and R7 become effective on the first day of the first calendar quarter, 12 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.~~

   ~~Except as indicated below, Requirements R2 through R6 and Requirement R8 shall become effective on the first day of the first calendar quarter, 24 months after applicable regulatory approval. In those jurisdictions where regulatory approval is not required, all requirements, except as noted below, go into effect on the first day of the first calendar quarter, 24 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.~~

   ~~For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-4, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-4:~~

   - ~~P1-2 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)~~
   - ~~P1-3 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)~~
   - ~~P2-1~~
   - ~~P2-2 (above 300 kV)~~

- ~~P2-3 (above 300 kV)~~
- ~~P3-1 through P3-5~~
- ~~P4-1 through P4-5 (above 300 kV)~~
- ~~P5 (above 300 kV)~~

B. Requirements and Measures

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-~~010 and MOD-012 standards~~032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities.

~~**1.1.2.** Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months.~~

~~**1.1.3.**~~**1.1.2.** New planned Facilities and changes to existing Facilities.

~~**1.1.4.**~~**1.1.3.** Real and reactive Load forecasts.

~~**1.1.5.**~~**1.1.4.** Known commitments for Firm Transmission Service and Interchange.

~~**1.1.6.**~~**1.1.5.** Resources (supply or demand side) required for Load.

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within ~~their~~ its respective area, using data consistent with MOD-~~010 and MOD-012~~032, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in

Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

~~**2.1.3.** P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.~~

~~**2.1.4.**~~**2.1.3.** For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response :

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P0 and P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner’s portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be ~~studied~~assessed. Based upon this assessment, an~~The~~ ~~studies~~ analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

2.4.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum, those known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments, but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or ~~Special Protection Systems~~Remedial Action Schemes.
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the

Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

3.3. Contingency analyses for Requirement R3, Parts 3.1 ~~&~~and 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES shall be identified<u>,</u> and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. ~~If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.~~

<u>**M3.** Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.</u>

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer

simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a ~~Special Protection System~~ Remedial Action Scheme is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event (s) shall be conducted.

4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall :

4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

4.3.1.1. Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2. Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3. Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. ~~If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.~~

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and -Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data identified in Measures M1 through M8 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

1.3. Compliance Monitoring and Enforcement Program: As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Compliance Monitoring Period and Reset Timeframe:

Not applicable.

1.5. Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checks
- Compliance Violation Investigations
- Self-Report
- Complaints

1.6. Additional Compliance Information

None.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R1.	The responsible entity's System model failed to represent one of the Requirement R1, Parts 1.1.1 through 1.1.~~6~~5.	The responsible entity's System model failed to represent two of the Requirement R1, Parts 1.1.1 through 1.1.~~6~~5.	The responsible entity's System model failed to represent three of the Requirement R1, Parts 1.1.1 through 1.1.~~6~~5.	The responsible entity's System model failed to represent four or more of the Requirement R1, Parts 1.1.1 through 1.1.~~6~~5. OR The responsible entity's System model did not represent projected System conditions as described in Requirement R1. OR The responsible entity's System model did not use data consistent with that provided in accordance with the MOD-~~010 and MOD-012~~032 standard~~s~~ and other sources, including items represented in the Corrective Action Plan.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
0	February 8, 2005	BOT Approval	Revised
0	June 3, 2005	Fixed reference in M1 to read TPL-001-0 R2.1 and TPL-001-0 R2.2	Errata
0	July 24, 2007	Corrected reference in M1. to read TPL-001-0 R1 and TPL-001-0 R2.	Errata
0.1	October 29, 2008	BOT adopted errata changes; updated version number to "0.1"	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote 'b' pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
		TPL-001-3 was created after the Board of Trustees approved the revised footnote 'b' in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	TBD	Adopted by the NERC Board of Trustees.	Revised To address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

Table 1 – Steady State & Stability Performance Planning Events

Steady State & Stability:

a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur.

b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0.

c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event.

d. Simulate Normal Clearing unless otherwise specified.

e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

Steady State Only:

f. Applicable Facility Ratings shall not be exceeded.

g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner.

h. Planning event P0 is applicable to steady state only.

i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements.

Stability Only:

j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P0 No Contingency	Normal System	None	N/A	EHV, HV	No	No
P1 Single Contingency	Normal System	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single Pole of a DC line	SLG			
P2 Single Contingency	Normal System	1. Opening of a line section w/o a fault [7]	N/A	EHV, HV	No[9]	No[12]
		2. Bus Section Fault	SLG	EHV	No[9]	No
				HV	Yes	Yes
		3. Internal Breaker Fault[8] (non-Bus-tie Breaker)	SLG	EHV	No[9]	No
				HV	Yes	Yes
		4. Internal Breaker Fault (Bus-tie Breaker)[8]	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P3 Multiple Contingency	Loss of generator unit followed by System adjustments[9]	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single pole of a DC line	SLG			
P4 Multiple Contingency *(Fault plus stuck breaker[10])*	Normal System	Loss of multiple elements caused by a stuck breaker[10](non-Bus-tie Breaker) attempting to clear a Fault on one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
		6. Loss of multiple elements caused by a stuck breaker[10] (Bus-tie Breaker) attempting to clear a Fault on the associated bus	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P5 Multiple Contingency *(Fault plus ~~relay~~non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant ~~relay[13]~~component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
P6 Multiple Contingency *(Two overlapping singles)*	Loss of one of the following followed by System adjustments.[9] 1. Transmission Circuit 2. Transformer [5] 3. Shunt Device[6] 4. Single pole of a DC line	Loss of one of the following: 1. Transmission Circuit 2. Transformer[5] 3. Shunt Device[6]	3Ø	EHV, HV	Yes	Yes
		4. Single pole of a DC line	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P7 Multiple Contingency *(Common Structure)*	Normal System	The loss of: 1. Any two adjacent (vertically or horizontally) circuits on common structure [11] 2. Loss of a bipolar DC line	SLG	EHV, HV	Yes	Yes

Table 1 – Steady State & Stability Performance Extreme Events

Steady State & Stability

For all extreme events evaluated:

a. Simulate the removal of all elements that Protection Systems and automatic controls are expected to disconnect for each Contingency.

b. Simulate Normal Clearing unless otherwise specified.

Steady State	Stability
1. Loss of a single generator, Transmission Circuit, single pole of a DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, single pole of a different DC Line, shunt device, or transformer forced out of service prior to System adjustments. 2. Local area events affecting the Transmission System such as: a. Loss of a tower line with three or more circuits.[11] b. Loss of all Transmission lines on a common Right-of-Way[11]. c. Loss of a switching station or substation (loss of one voltage level plus transformers). d. Loss of all generating units at a generating station. e. Loss of a large Load or major Load center. 3. Wide area events affecting the Transmission System based on System topology such as: a. Loss of two generating stations resulting from conditions such as: i. Loss of a large gas pipeline into a region or multiple regions that have significant gas-fired generation.	1. With an initial condition of a single generator, Transmission circuit, single pole of a DC line, shunt device, or transformer forced out of service, apply a 3Ø fault on another single generator, Transmission circuit, single pole of a different DC line, shunt device, or transformer prior to System adjustments. 2. Local or wide area events affecting the Transmission System such as: a. 3Ø fault on generator with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing. b. 3Ø fault on Transmission circuit with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing. c. 3Ø fault on transformer with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing. d. 3Ø fault on bus section with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing. e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

ii. Loss of the use of a large body of water as the cooling source for generation. iii. Wildfires. iv. Severe weather, e.g., hurricanes, tornadoes, etc. v. A successful cyber attack. vi. Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. ~~e.~~i. 3Ø internal breaker fault. ~~f.~~j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss. 2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria. 3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss. 4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service. 5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. 6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground. 7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point. 8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker. 9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered.

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing.
11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less.
12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.
13. ~~Applies~~For purposes of this standard, non-redundant components of a Protection System to ~~the following~~consider are as follows: a. A single protective relay which responds to electrical quantities, without an alternative (which may or may not respond to electrical quantities) that provides comparable Normal Clearing times; b. A single communications system associated with protective functions~~ or types: pilot (#85), distance (#21), differential (#87), current (#50, 51,~~, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing (an exception is a single communications system that is both monitored and ~~67),~~reported at a Control Center); c. A single station dc supply associated with protective functions required for Normal Clearing (an exception is a single station dc supply that is both monitored and reported at a Control Center for both low voltage ~~(#27 & 59), directional (#32, & 67), and tripping (#86, & 94).~~and open circuit); d. A single control circuitry (including auxiliary relays and lockout relays) associated with protective functions, from the dc supply through and including the trip coil(s) of the circuit breakers or other interrupting devices, required for Normal Clearing (the trip coil may be excluded if it is both monitored and reported at a Control Center).

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. .The process must include the following:

1. Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues
2. Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:
    a. Date, time, and location for the meeting
    b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
    c. Provisions for a stakeholder comment period
3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
    a. System Load level and estimated annual hours of exposure at or above that Load level
    b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency
2. Amount of Non-Consequential Load Loss with:

   a. The estimated number and type of customers affected
   b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community
3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance
4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance
5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12
6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12
7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12
8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

<u>III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required</u>

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

1. The voltage level of the Contingency is greater than 300 kV
   a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or
   b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)
2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

~~C. Measures~~

~~**M1.** Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with MOD-010 and MOD-012, including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.~~

~~**M2.M1.** Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.~~

~~**M3.M1.** Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.~~

~~**M4.M1.** Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.~~

~~**M5.M1.** Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.~~

~~**M6.** Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.~~

~~**M7.** Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7.~~

~~Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.~~

Exhibit B

Implementation Plan

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Implementation Plan

Project 2015-10 Single Points of Failure
Reliability Standard TPL-001-5

Applicable Standard(s)

- TPL-001-5 – Transmission System Planning Performance Requirements

Requested Retirement(s)

- TPL-001-4 – Transmission System Planning Performance Requirements

Prerequisite Standard(s)
None

Applicable Entities

- Planning Coordinator
- Transmission Planner

Background
Reliability Standard TPL-001-5 revises the prior version of the TPL-001 standard in three key respects:

- To address reliability issues concerning the study of single points of failure in Protection Systems, as identified in:
  - Federal Energy Regulatory Commission (FERC) Order No. 754, issued on September 15, 2011; and
  - the report dated September 2015 by two subcommittees under NERC Planning Committee , the System Protection and Control Subcommittee and System Analysis and Modeling Subcommittee, titled *Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request;*
- To address directives from FERC Order No. 786 (October 17, 2013) approving Reliability Standard TPL-001-4, relating to:
  - modeling known outages with a duration of less than six months (paragraph 40); and
  - adding stability analysis for the outage of major Transmission equipment with a lead time of one year or more (paragraph 89); and;
- To replace references to the Reliability Standards MOD-010 and MOD-012, which have been superseded by MOD-032.

General Considerations

The standard will become effective 36 months following regulatory approval. The 36-month period provides time for Planning Coordinators and Transmission Planners to develop, among other things:

- A procedure or technical rationale for selecting known outages of generation and Transmission Facilities;
- Coordination with protection engineers to obtain the necessary data to perform the single points of failure analysis required by the standard; and
- Additional analysis required due to changes in the standard.

Following this 36 month period, an additional 24-month period allows time for the development of Corrective Action Plans (CAPs) under TPL-001-5 for Category P5 planning events involving single points of failure in Protection Systems.

Transmission Planners and Planning Coordinators shall have an additional 48 months beyond the time by which CAPs must be developed to comply with the bolded part of Requirement R2, Part 2.7 that states: "Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments **but the planned System shall continue to meet the performance requirements in Table 1**" for P5 planning events for non-redundant components of a Protection System identified in footnote 13 items a, b, c, and d.

This implementation plan reflects consideration that Planning Coordinators and Transmission Planners will need time to conduct the new studies and analyses in order to coordinate with asset owners and protection engineers to identify appropriate CAP actions and establish the associated timetables for completion. This includes any necessary CAP(s) to address System performance issues for studies involving Table 1 Category P5 (Fault plus non-redundant component of a Protection System failure to operate) required by TPL-001-5 Requirement R2, Part 2.7 for the non-redundant components of a Protection System identified in TPL-001-5 Table 1 Footnote 13.

Please see Figure 1 Implementation Timeline below for an illustration of the 108-month implementation timeline in those jurisdictions where governmental approval is required.

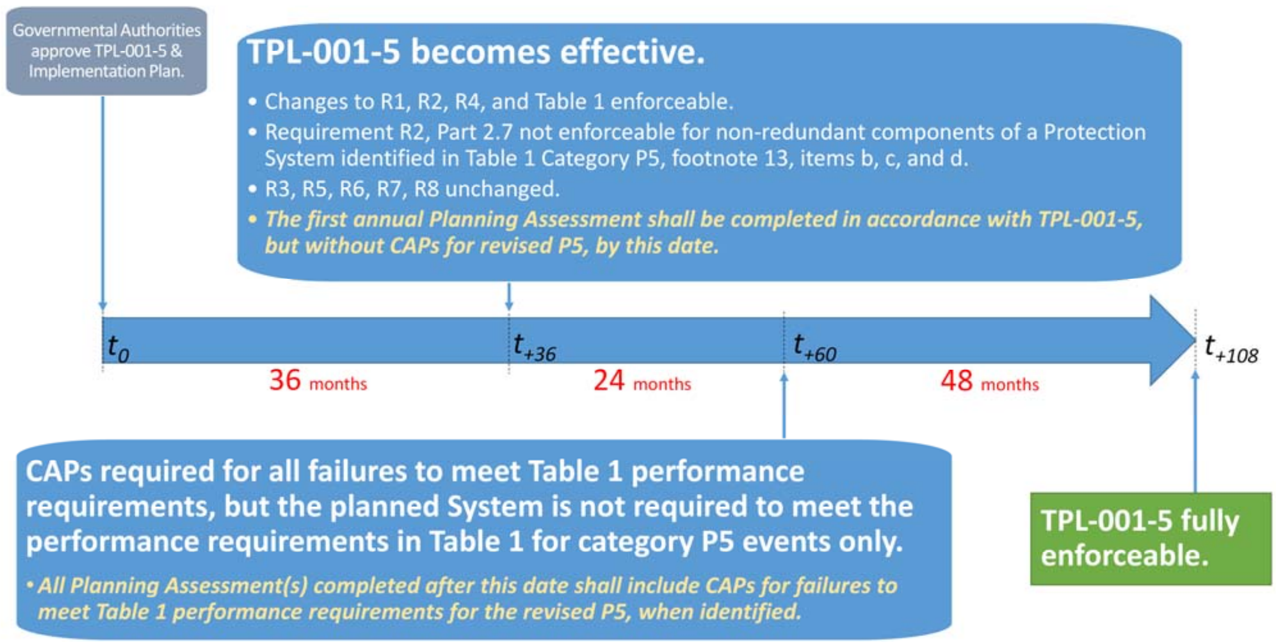

Figure 1 Implementation Plan Timeline

Effective Date

TPL-001-5 – Transmission System Planning Performance Requirements

Where approval by an applicable governmental authority is required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Compliance Date for TPL-001-5 Requirement 2, Part 2.7 associated with Table 1 Category P5 Footnote 13 items a, b, c, and d

Entities shall not be required to comply with Requirement R2, Part 2.7 for the Table 1 Category P5 planning event for the non-redundant components of a Protection System identified in footnote 13 items a, b, c, and d until 24 months after the effective date of Reliability Standard TPL-001-5.

For CAPs developed to address failures to meet Table 1 performance requirements for the P5 planning event for the non-redundant components of a Protection System identified in footnote 13 items a, b, c, and d, entities shall not be required to comply until 72 months after the effective date of Reliability Standard TPL-001-5 with the bolded part of Requirement R2, Part 2.7 that states: "Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments **but the planned System shall continue to meet the performance requirements in Table 1.**"

Initial Performance of Periodic Requirements

Each responsible entity shall complete the first annual Planning Assessment in accordance with TPL-001-5 (without CAP(s) for the revised P5 planning event) by the effective date of the standard.

Each responsible entity shall develop any required CAP(s) under Requirement R2, Part 2.7 associated with the non-redundant components of a Protection System identified in Table 1 Category P5 Footnote 13 items a, b, c, and d by 24 months after the effective date of the standard.

Retirement Date

TPL-001-4 – Transmission System Planning Performance Requirements

Reliability Standard TPL-001-4 shall be retired immediately prior to the effective date of TPL-001-5 in the particular jurisdiction in which the revised standard is becoming effective.

Exhibit C

Order No. 672 Criteria

Exhibit C — Order No. 672 Criteria — Proposed Reliability Standard TPL-001-5

Order No. 672 Criteria

In Order No. 672,[1] the Commission identified a number of criteria it will use to analyze Reliability Standards proposed for approval to ensure they are just, reasonable, not unduly discriminatory or preferential, and in the public interest. The discussion below identifies these factors and explains how the proposed Reliability Standard has met or exceeded the criteria:

1. **Proposed Reliability Standards must be designed to achieve a specified reliability goal and must contain a technically sound means to achieve that goal.[2]**

The purpose of proposed Reliability Standard TPL-001-5 is to establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

Reliability Standard TPL-001-5 requires applicable entities to perform an annual Planning Assessment of its portion of the BES covering a number of System conditions and Contingencies described in the standard. Proposed Reliability Standard TPL-001-5 enhances reliability by providing for more comprehensive consideration of Protection System single points of failure, known outages, and the unavailability of long lead-time equipment in planning studies. Specifically, proposed Reliability Standard TPL-001-5 improves upon currently effective Reliability Standard TPL-001-4 by revising the existing Table 1 planning and extreme events to require a more complete, risk-based analysis of how the failure of a non-redundant component of a Protection System would affect a planning entity's System. These revisions are based on recommendations following the analysis of data collected under request for data under

[1] *Rules Concerning Certification of the Electric Reliability Organization; and Procedures for the Establishment, Approval, and Enforcement of Electric Reliability Standards*, Order No. 672, FERC Stats. & Regs. ¶ 31,204, *order on reh'g*, Order No. 672-A, FERC Stats. & Regs. ¶ 31,212 (2006).

[2] Order No. 672 at P 321, 324.

Section 1600 of the NERC Rules of Procedure. The proposed standard also addresses the Commission's standard modification directives from Order No. 786 by: (i) requiring a more comprehensive analysis of known outages in planning studies; and (ii) requiring entities to consider, in Stability analysis, the impacts of the possible unavailability of long lead time equipment, consistent with the entity's spare equipment strategy.

2. **Proposed Reliability Standards must be applicable only to users, owners and operators of the bulk power system, and must be clear and unambiguous as to what is required and who is required to comply.**[3]

The proposed Reliability Standard is clear and unambiguous as to what is required and who is required to comply, in accordance with Order No. 672. Proposed Reliability Standard TPL-001-5 continues to apply to Planning Coordinators and Transmission Planners. The proposed standard clearly articulates the actions that each entity must take to comply.

3. **A proposed Reliability Standard must include clear and understandable consequences and a range of penalties (monetary and/or non-monetary) for a violation.**[4]

The Violation Risk Factors ("VRFs") and Violation Severity Levels ("VSLs") for proposed Reliability Standard TPL-001-5, as reflected in **Exhibit A,** are substantively unchanged from currently effective Reliability Standard TPL-001-4. The VRFs and VSLs comport with NERC and Commission guidelines related to their assignment. The VSLs are consistent with the corresponding Requirements and do not use any ambiguous terminology, thereby supporting uniformity and consistency in the determination of similar penalties for similar violations. For these reasons, the proposed Reliability Standard includes clear and understandable consequences in accordance with Order No. 672.

---

[3] Order No. 672 at P 322, 325.

[4] Order No. 672 at P 326.

4. A proposed Reliability Standard must identify clear and objective criterion or measure for compliance, so that it can be enforced in a consistent and non-preferential manner.[5]

The proposed Reliability Standard includes Measures that support the proposed standard's Requirements by clearly identifying what is required and how the Requirements will be enforced. These Measures, which remain substantively unchanged from the Measures in currently effective Reliability Standard TPL-001-4, help provide clarity regarding how the Requirements will be enforced, and help ensure that the Requirements will be enforced in a clear, consistent, and non-preferential manner and without prejudice to any party.

5. Proposed Reliability Standards should achieve a reliability goal effectively and efficiently — but do not necessarily have to reflect "best practices" without regard to implementation cost or historical regional infrastructure design.[6]

The proposed Reliability Standard achieves its reliability goals effectively and efficiently in accordance with Order No. 672. The proposed standard provides for more comprehensive planning studies, thereby contributing to a more reliable BES. First, the proposed standard provides for a more complete consideration of factors for selecting which known outages will be included in Near-Term Transmission Planning Horizon studies. The revisions reflected in proposed Reliability Standard TPL-001-5 effectively address the Commission's concern that the exclusion of known outages of less than six months in TPL-001-4 could result in outages of significant facilities not being studied and account for variations in regional practices. Second, the proposed Reliability Standard provides for a more comprehensive analysis of the potential impacts of Protection System single points of failure. Third, the proposed standard requires the entity assess the impact of the possible unavailability of long lead time equipment, consistent with the entity's spare equipment strategy, in its Stability analysis. Consistent with the currently

---

5 Order No. 672 at P 327.

6 Order No. 672 at P 328.

effective standard, entities retain flexibility to select appropriate mitigation measures in the event System performance issues are identified. The proposed standard thereby achieves its reliability goal effectively and efficiently.

6. **Proposed Reliability Standards cannot be "lowest common denominator," *i.e.*, cannot reflect a compromise that does not adequately protect Bulk-Power System reliability. Proposed Reliability Standards can consider costs to implement for smaller entities, but not at consequences of less than excellence in operating system reliability.**[7]

The proposed Reliability Standard does not reflect a "lowest common denominator" approach. To the contrary, the revisions reflected in proposed Reliability Standard TPL-001-5 provide significant benefits for the reliability of the Bulk Power System by providing for more comprehensive planning studies: The proposed Reliability Standard does not sacrifice excellence in operating system reliability for costs associated with implementation of the Reliability Standard.

7. **Proposed Reliability Standards must be designed to apply throughout North America to the maximum extent achievable with a single Reliability Standard while not favoring one geographic area or regional model. It should take into account regional variations in the organization and corporate structures of transmission owners and operators, variations in generation fuel type and ownership patterns, and regional variations in market design if these affect the proposed Reliability Standard.**[8]

The proposed Reliability Standard applies throughout North America and does not favor one geographic area or regional model.

8. **Proposed Reliability Standards should cause no undue negative effect on competition or restriction of the grid beyond any restriction necessary for reliability.**[9]

The proposed Reliability Standard has no undue negative effect on competition. The proposed Reliability Standard requires the same performance by each of applicable entity. The

---

[7] Order No. 672 at PP 329, 330.

[8] Order No. 672 at P 331.

[9] Order No. 672 at P 332.

proposed Reliability Standard does not unreasonably restrict the available generation or transmission capability or limit use of the Bulk-Power System in a preferential manner.

9. The implementation time for the proposed Reliability Standard is reasonable.[10]

The proposed effective date for the proposed Reliability Standard is just and reasonable and appropriately balances the urgency in the need to implement the proposed Reliability Standard against the reasonableness of the time allowed for those who must comply to develop necessary procedures, software, facilities, staffing or other relevant capability. NERC proposes an effective date for TPL-001-5 that is the first day of the first calendar quarter that is 36 months after regulatory approval. Reliability Standard TPL-001-4 would be retired immediately prior to the effective date of TPL-001-5.

Under the TPL-001-5 implementation plan, entities have additional time to come into compliance with certain Requirements related to the study of single points of failure on Protection Systems. Specifically, planning entities would have an additional 24 months after the effective date of the standard to develop Corrective Action Plans under Requirement R2, Part 2.7 for the Table 1 Category P5 planning event involving the non-redundant components of a Protection System specified in Footnote 13 items a, b, c, and d. Further, entities shall have an additional 72 months after the effective date of the standard to comply with the underlined part of Requirement R2, Part 2.7 that states: "Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1."

The proposed effective date and phased compliance dates are reflected in the proposed implementation plan, attached as **Exhibit B**.

---

[10] Order No. 672 at P 333.

10. The Reliability Standard was developed in an open and fair manner and in accordance with the Commission-approved Reliability Standard development process.[11]

The proposed Reliability Standard was developed in accordance with NERC's Commission-approved, ANSI-accredited processes for developing and approving Reliability Standards. **Exhibit G** includes a summary of the Reliability Standard development proceedings, and details the processes followed to develop the proposed Reliability Standard. These processes included, among other things, comment periods, pre-ballot review periods, and balloting periods. Additionally, all meetings of the standard drafting team were properly noticed and open to the public.

11. NERC must explain any balancing of vital public interests in the development of proposed Reliability Standards.[12]

NERC has identified no competing public interests regarding the request for approval of the proposed Reliability Standard. No comments were received indicating the proposed Reliability Standard is in conflict with other vital public interests.

12. Proposed Reliability Standards must consider any other appropriate factors.[13]

No other factors relevant to whether the proposed Reliability Standard is just, reasonable, not unduly discriminatory or preferential were identified.

Analysis of Violation Risk Factors

and

Violation Severity Levels

Violation Risk Factor and Violation Severity Level Justifications

Project 2015-10 Single Points of Failure TPL-001

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for Requirement R4 in Project 2015-10 and Single Points of Failure TPL-001. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report

FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard
FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards
FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level
Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation
Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the "default" for penalty calculations.

VRF Justification for TPL-001-5, Requirement R1

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R1

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R2

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R2

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R3

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R3

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R4

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R4

Project 2015-10 Single Points of Failure TPL-001

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
TPL-001-4, Requirement R1 **R1.** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-010 and MOD-012 standards, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. **1.1** System models shall represent: **1.1.1.** Existing Facilities	TPL-001-5, Requirement R1 **R1.** Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*	Requirement R1 body has been updated to reference MOD-032 standard number in body of requirement. Requirement R1, Part 1.1.2 and subparts have been deleted. Selection of known outages will be addressed in Requirement R2, Parts 2.1.4 and 2.4.4.

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
1.1.2. Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months. **1.1.3.** New planned Facilities and changes to existing Facilities **1.1.4.** Real and reactive Load forecasts **1.1.5.** Known commitments for Firm Transmission Service and Interchange **1.1.6.** Resources (supply or demand side) required for Load	**1.1.** System models shall represent: **1.1.1.** Existing Facilities. **1.1.2.** New planned Facilities and changes to existing Facilities. **1.1.3.** Real and reactive Load forecasts. **1.1.4.** Known commitments for Firm Transmission Service and Interchange. **1.1.5.** Resources (supply or demand side) required for Load.	
TPL-001-4, Requirement R2 Parts 2.1, 2.1.1, 2.1.2, Parts 2..2, 2.2.1 Part 2.3 Parts 2.4, 2.4.1, 2.4.2 Part 2.5 Parts 2.6, 2.6.1, 2.6.2 Parts 2.7.2, 2.7.3, 2.7.4	TPL-001-5, Requirement R2 Parts 2.1, 2.1.1, 2.1.2, Parts 2..2, 2.2.1 Part 2.3 Parts 2.4, 2.4.1, 2.4.2 Part 2.5 Parts 2.6, 2.6.1, 2.6.2 Parts 2.7.2, 2.7.3, 2.7.4	No modifications made.

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
Parts 2.8, 2.8.1, 2.8.2	Parts 2.8, 2.8.1, 2.8.2	
TPL-001-4, Requirement R2 R2 Part 2.1.4 2.1.4 For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response : • Real and reactive forecasted Load. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of known Transmission outages.	TPL-001-5, Requirement R2 R2 Part 2.1.3 2.1.3 For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response: • Real and reactive forecasted Load. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability.	Requirement R2, Part 2.1.4 moved to Requirement R2, Part 2.1.3

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
	• Generation additions, retirements, or other dispatch scenarios. • Controllable Loads and Demand Side Management. • Duration or timing of known Transmission outages.	
TPL-001-4, Requirement R2 2.1.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.	TPL-001-5, Requirement R2 2.1.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P0 and P1 categories identified in Table 1 with	<u>Requirement R2 Part 2.1.3 moved to Requirement R2 Part 2.1.4</u> A properly planned Transmission system should facilitate maintenance outages without Non-Consequential Load Loss, maintain a stable System without Cascading and uncontrolled islanding. (FERC Order 786, Paragraph 41). Therefore, consistent with the principle of TPL-001-5 Requirement R3, Part 3.4 which requires the Transmission Planner and Planning Coordinator to identify those planning events in Table 1 that are expected to produce more severe System

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
	the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1	impacts on its portion of the BES, only those P1 events in Table 1 expected to produce more severe System impacts on its portion of the BES are to be assessed for System models that include known outages pursuant to Requirement R2, Part 2.1.4.
TPL-001-4, Requirement R2 2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.	TPL-001-5, Requirement R2 2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to	<u>Requirement R2, Part 2.1.5 Document internal conforming as reflecting in R2, Part 2.4.5</u>

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
	experience during the possible unavailability of the long lead time equipment.	
TPL-001-4, Requirement R2 2.4.3. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance: • Load level, Load forecast, or dynamic Load model assumptions. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios.	TPL-001-5, Requirement R2 2.4.3. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance: • Load level, Load forecast, or dynamic Load model assumptions. • Expected transfers. • Expected in service dates of new or modified Transmission Facilities. • Reactive resource capability. • Generation additions, retirements, or other dispatch scenarios.	Requirement R2, Part 2.4.3 has been moved back to 2.4.3 as it was in TPL-001-4.

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
	TPL-001-5, Requirement R2 2.4.4. When known outage(s) of generation or Transmission Facility(ies) are planned in the Near-Term Planning Horizon, the impact of selected known outages on System performance shall be assessed. These known outage(s) shall be selected for assessment consistent with a documented outage coordination procedure or technical rationale by the Planning Coordinator or Transmission Planner. Known outage(s) shall not be excluded solely based upon outage duration. The assessment shall be performed for the P1 categories identified in Table 1 with the System peak or Off-Peak conditions that the System is expected to experience when the known outage(s) are planned. This assessment shall include, at a minimum, those known outages expected to produce more severe System impacts on the Planning Coordinator or Transmission Planner's portion of the BES. Past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as	<u>TPL-001-5, Requirement R2, Part 2.4.4</u> <u>TPL-001-4, Part 2.4.3 moved to TPL-001-5, Part 2.4.4</u> Modified the standard to add a Stability analysis requirement for P1 events in Table 1, with known outages under appropriate System conditions, that includes similar language to that used for the steady state analysis stated in Requirement R2, Part 2.1.4. For reasons similar to those justifying changes to Requirement R2 Part 2.1.4, the Transmission Planner and Planning Coordinator shall identify those P1 events in Table 1 expected to produce more severe System impacts on its portion of the BES to be assessed for System models that include known outages pursuant to Requirement R2 Part 2.4.4.

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
	those following P3 or P6 category events in Table 1.	
	TPL-001-5, Requirement R2 **2.4.5.** When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.	<u>TPL-001-5, Requirement R2, Part 2.4.5</u> Consistent with FERC Order 786 Para 89, modified the standard to add Requirement R2, Part 2.4.5, which includes similar language to that used for the steady-state analysis stated in Requirement R2, Part 2.1.5 to address stability analysis for spare equipment strategy.
TPL-001-4, Requirement R2 Requirement R2 Part 2.7	TPL-001-5, Requirement R2 Requirement R2 Part 2.7 **2.7** For planning events shown in Table 1, when the analysis indicates an inability of the	<u>TPL-001-5, Requirement R2,</u> <u>Requirement R2, Part 2.7</u>

Standard: TPL-001-5		
Requirement in Approved Standard	**Translation to New Standard or Other Action**	**Description and Change Justification**
2.7 For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:	System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.3 and 2.4.3. The Corrective Action Plan(s) shall:	Changed Requirement subpart reference in Requirement 2, Part R2.7 in standard.
TPL-001-4, Requirement R2, Part 2.7 2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include: • Installation, modification, retirement, or	TPL-001-5, Requirement R2, Part 2.7 2.7.1. Preface

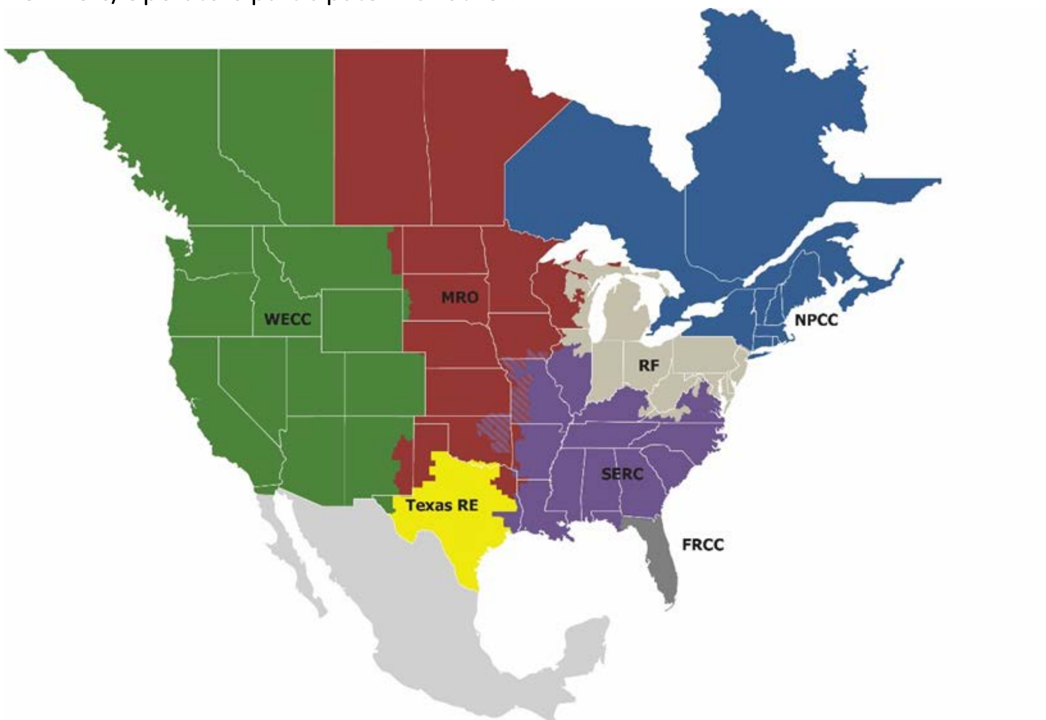
The vision for the Electric Reliability Organization (ERO) Enterprise, which is comprised of the North American Electric Reliability Corporation (NERC) and the seven Regional Entities (REs), is a highly reliable and secure North American bulk power system (BPS). Our mission is to assure the effective and efficient reduction of risks to the reliability and security of the grid.

The North American BPS is divided into seven RE boundaries as shown in the map and corresponding table below. The multicolored area denotes overlap as some load-serving entities participate in one Region while associated Transmission Owners/Operators participate in another.



FRCC	Florida Reliability Coordinating Council
MRO	Midwest Reliability Organization
NPCC	Northeast Power Coordinating Council
RF	ReliabilityFirst
SERC	SERC Reliability Corporation
Texas RE	Texas Reliability Entity
WECC	Western Electricity Coordinating Council

Executive Summary

Project 2015-10 Technical Rationale provides the background and rationale for proposed revisions to Reliability Standard TPL-001-4. The proposed revisions address reliability issues concerning the study of single points of failure (SPF) on Protection Systems from FERC Order No. 754, directives from FERC Order No. 786 regarding planned maintenance outages and stability analysis for spare equipment strategy , and replaces references to the MOD-010 and MOD-012 standards with the MOD-032 Reliability Standard.

Key Concepts of FERC Order No. 754

The Standard Drafting Team (SDT) took into account the recommendations for modifying NERC Reliability Standard TPL-001-4 identified in both the SPCS and SAMS report titled *Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request* and the *Informational Filing of the North American Electric Reliability Corporation in Response to Order No. 754* to the FERC. In "Table 1 – Steady State and Stability Performance Planning Events," the Category P5 event incorporates Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System. In "Table 1 – Steady State and Stability Performance Extreme Events," breaker failure and failure of a non-redundant component of a Protection System are differentiated. The SDT recognizes that sequence and timing of Protection System action leading to Delayed Fault Clearing may be quite different between the two causalities, and also that fault severity and acceptable consequence of failure of a non-redundant component of a Protection System should be differentiated. Footnote 13 of the "Table 1 – Steady State & Stability Performance Footnotes" describes the non-redundant Protection System components to be considered for Category P5 Planning Events and Stability Extreme Events.

Key Concepts of FERC Order No. 786

The SDT considered the Commission's concern that the outages of significant facilities less than six months could be overlooked for planning purposes, that Category P3 and P6 do not sufficiently cover planned maintenance outages, and the Near-Term Transmission Planning Horizon requires annual assessments using Year One or year two, and year five, and known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon. Proposed revisions remove the six month outage duration, shift the consideration of known outages from Requirement R1, which requires what System models shall represent, to Requirement R2, Parts 2.1 and 2.4, which require the study and assessment of known outages. Further, proposed revisions include a requirement to document an outage coordination procedure or the technical rationale for the determination of which known outages to study. Proposed revisions also included the addition of stability assessment for long lead equipment that does not have a spare.

Summary of proposed revisions

- Requirement R1 – Updated for MOD-032-1 standard.
- Requirement R1, Part 1.1.2 – Removed this requirement.
- Requirement R2, Part 2.1.4 – Added model conditions for steady state analysis of P0 and P1 events for known outages.
- Requirement R2, Part 2.4.4 – Added model conditions for stability analysis of P1 events for known outages.
- Requirement R2, Part 2.4.5 – Added stability analysis requirement for long lead time equipment unavailability.
- Requirement R3, Part 3.2 – Document internal conforming clean-up to incorporate the last sentence of Part 3.5.

- Requirement R4, Part 4.2 – Document internal conforming clean-up to incorporate the last sentence of Part 4.5.
- Table 1 – Modified Category P5 event to include SPF.
- Table 1 – Modified Extreme Events, Stability column to differentiate SPF from stuck breaker.
- Table 1 – Modified Footnote 13 to specify the SPF that should be considered.

Introduction

NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) is being modified to address reliability issues and standard modification directives contained in FERC Order No. 754[1] and FERC Order No. 786.[2] Proposed Reliability Standard TPL-001-5 revises the TPL-001 standard to address the reliability risks posed by SPF on Protection Systems.

Background

FERC Order No. 754

FERC Order No. 754 directed NERC to study the reliability risk associated with SPF in Protection Systems. As a follow-up to a NERC Technical Conference where the risks and concerns associated with SPF were discussed, the NERC System Protection and Control Subcommittee (SPCS) and the System Analysis and Modelling Subcommittee (SAMS) conducted an assessment of Protection System SPF in response to FERC Order No. 754, including analysis of data collected pursuant to a request for data or information under Section 1600 of the NERC Rules of Procedure. The SPCS and SAMS report titled *Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request* and the *Informational filing of the North American Electric Reliability Corporation in Response to Order No. 754* to the FERC provide extensive general discussion about the reliability risks associated with a SPF.

The SDT strongly considered the recommendations of the SPCS and SAMS report, recognizing that the purpose of that report was to determine whether a reliability concern existed demanding NERC to address the study of SPF on Protection Systems. The formation of the Project 2015-10 directly resulted from the SPCS and SAMS report recommendations. However, the SDT's obligation was to consider the reported recommendations and translate them into proposed TPL-001-5 Reliability Standard requirements that are meaningful to Planning Coordinators and Transmission Planners for performance of annual TPL Planning Assessments which adequately account for the reliability risk posed by SPF on Protection Systems.

FERC Order No. 786

In FERC Order No. 786, FERC directed NERC to address two issues. The first issue is the concern that the six month outage duration threshold could exclude planned maintenance outages of significant facilities from future planning assessments. FERC directed NERC to modify TPL-001-4 to address this concern. The second issue involves adding clarity regarding dynamic assessment of outages of critical long lead time equipment, consistent with the entity's spare equipment strategy. FERC directed NERC to consider this issue upon its next review of TPL-001-4. The NERC SAMS developed a white paper documenting the technical analysis conducted by SAMS to address the two directives contained in the FERC Order No. 786. The white paper provides extensive general discussion regarding the directives.

Section 1: Single Points of Failure on Protection Systems (FERC Order No. 754)

NERC Advisory

On March 30, 2009, NERC issued an advisory[3] report notifying the industry that a SPF issue had caused three significant system disturbances in 5 years.

Transmission Owners, Generation Owners, and Distribution Providers owning Protection Systems installed on the Bulk Electric System (BES) were advised to address SPF on their Protection Systems when identified in routine system evaluations to prevent N-1 transmission system contingencies from evolving into more severe or even extreme events.

These entities were additionally advised to begin preparing an estimate of the resource commitment required to review, re-engineer, and develop a workable outage and construction schedule to address SPF on their Protection Systems.

FERC Order No. 754

In FERC Order No. 754 Paragraph 20, FERC directed NERC to "to make an informational filing within six months of the date of the issuance of this Final Rule explaining whether there is a further system protection issue that needs to be addressed and, if so, what forum and process should be used to address that issue and what priority it should be accorded relative to other reliability initiatives planned by NERC."

FERC Technical Conference

A FERC technical conference concerning the Commission's Order 754 titled Staff Meeting on Single Points of Failure on Protection Systems was held on October 24-25, 2011 at FERC in Washington, DC.

At the technical conference, the attendees discussed the SPF issue and narrowed their concerns into four consensus points:

- The concern with assessment of SPF is a performance-based issue, not a full redundancy issue.
- The existing approved standards address assessments of SPF.
- Assessments of SPF of non-redundant primary protection (including backup) systems need to be sufficiently comprehensive.
- Lack of sufficiently comprehensive assessments of non-redundant primary Protection Systems is a reliability concern.

Joint SPCS-SAMS Report

One outcome of the FERC technical conference was that NERC would conduct a data collection effort to provide a broad factual foundation that could aid in assessing the reliability risks posed by SPF. The NERC Board of Trustees approved the request for data or information under Section 1600 of the NERC Rules of Procedure ("Order No. 754 Data Request") on August 16, 2012.

In September 2015, SPCS and SAMS issued a report to the NERC Planning Committee (PC) and Operating Committee (OC), summarizing the information collected under the Order No. 754 Data Request. The assessment confirmed the existence of a reliability risk associated with SPF in Protection Systems that warrants further action.

[3] *See [Industry Advisory: Single Point of Failure](http://www.nerc.com/files/Final_Order_754_Informational_Filing_3-15-12_complete.pdf)*
http://www.nerc.com/files/Final_Order_754_Informational_Filing_3-15-12_complete.pdf

To address this risk, the SPCS and the SAMS considered a variety of alternatives and concluded that the most appropriate recommendation that aligns with FERC Order No. 754 directives and maximizes reliability of Protection System performance is to modify NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process.

The SDT strongly considered the recommendations of the SPCS and SAMS report, as specified by the Project 2015-10 Single Points of Failure Standards Authorization Request (SAR). The SDT recognized that its obligation was to consider the reported recommendations and translate them into proposed TPL-001-5 Reliability Standard requirements that are meaningful to Planning Coordinators and Transmission Planners for performance of annual TPL Planning Assessments. The SPCS and SAMS report recommendations, as well as how they have been addressed in proposed TPL-001-5 by the Project 2015-10 SDT are summarized in the following section.

Revisions to TPL-001-4

Single Points of Failure – Category P5 Planning Events

The SPCS and SAMS report states, “Analysis of the data demonstrates the existence of a reliability risk associated with single points of failure in protection systems that warrants further action. The analysis shows that the risk from single point of failure is not an endemic problem and instances of single point of failure exposure are lower on higher voltage systems. However, the risk is sufficient to warrant further action. Risk-based assessment should be used to identify protection systems of concern (i.e., locations on the BES where there is a susceptibility to cascading if a protection system single point of failure exists)”.

The modifications to the Category P5 Planning event description are intended to be aligned with the changes to the Table 1, Footnote 13. The SDT has modified Table 1, Footnote 13 to capture the SPCS/SAMS recommendations for Category P5 events, which expands beyond the previously limited set of relays identified in TPL-001-4, to capture the identified SPF of concern. Footnote 13 describes the non-redundant Protection System components to be considered for Category P5 Planning Events, and is discussed further below.

The Table 1 Category P5 event describes a Contingency where a single line-to-ground (SLG) fault occurs and Delayed Fault Clearing results due to the failure of the Protection System, protecting the Faulted element, to operate as designed. Typically, the two most important aspects of the P5 event that affect simulation are the magnitude of SLG fault current and the mode of Protection System failure leading to Delayed Fault Clearing. The latter is especially important and the mode of Protection System failure details make the P5 event unique. The Transmission Planner or Planning Coordinator must be cognizant of the time period during which the Protection System removes Elements from service, as well as the sequence of their removal during isolation of the fault. By definition, Normal Clearing is not expected when a non-redundant component of a Protection System is simulated to have failed; the P5 event implies that the Protection System does not operate as designed to clear the SLG fault in the time normally expected with proper functioning of the installed Protection System. Therefore, when a non-redundant component of a Protection System fails, Delayed Fault Clearing results. This means that correct operation of the backup Protection System occurs with the intentionally designed time delay before fault clearing. Additionally, there may be significant differences in final System configuration due to the Protection System operation to clear the faulted Element. For example, more System Elements may be removed from service when the backup Protection System operates, consistent with Delayed Fault Clearing, than may be expected during primary Protection System operation expected for Normal Clearing. The expected time delays for Protection System operation are critical for proper simulation of the P5 event.

It is anticipated that the most cost-effective Corrective Action Plans to address unacceptable system performance for the P5 Planning Events will likely be to add Protection System component redundancy, consistent with the components to be considered in Footnote 13. Protection System redundancy changes to address Category P5

Event concerns should also reduce or even negate non-redundant components that need to be considered in assessing System performance resulting from simulation of the 2e-2h Extreme Events; hence, potentially mitigating many concerns.

Clarification: Why address SPF in TPL-001 and not create a new Reliability Standard for this purpose?

As part of the recommendations from the SPCS and SAMS report, the option to create a new Reliability Standard to address SPF in the Protection System was considered. Both a new TPL standard for planning-related studies and assessment, as well as a new Protection and Control standard to specify Protection System redundancy were debated by SPCS and SAMS. Ultimately, the recommendation of the SPCS and SAMS report, leading to the formation of the Project 2015-10 SDT, focused upon the simulation and study assessment of the Transmission system given non-redundant components of the Protection System instead of mandating a level of redundancy across a diverse set of equipment and utilities in North America.

It is important to emphasize that modifications to the TPL-001-5 Table 1 Category P5 Planning Event, the TPL-001-5 Table 1 Extreme Stability Events, and related changes to Table 1, Footnote 13 do not establish or mandate a level of redundancy for Protection Systems. Quite the contrary: the modifications presented in TPL-001-5 require planning entities to consider the non-redundant components of Protection Systems that may exist within their respective Systems, to execute appropriate studies, and to assess the impacts that these SPF may have upon the ability to meet Table 1 System performance requirements given Delayed Fault Clearing. TPL-001-5 does not mandate redundancy; TPL-001-5 requires that some non-redundancy components of a Protection System be considered during annual Planning Assessments.

Clarification: Why is consideration of fault duration significant for the P5 Planning Event?

A Protection System is designed to isolate faulted equipment within an expected time duration following fault initiation. When the Protection System does not operate as designed or fails to isolate faulted equipment within the time normally expected with its proper functioning, backup protection capabilities must act to clear the fault. The SDT recognized that Protection Systems used for backup protection are designed with intentional time delays that inherently allows primary protection to actuate first. This is consistent with the Table 1 Planning Event P5 which is characterized by its prescribed Delayed Fault Clearing. The SDT recognized that the sequencing, causality, and mode of failure of a non-redundant component of a Protection System leads to Delayed Fault Clearing by the operation of backup protection, whether local (e.g., breaker failure initiation) or remote (e.g., remote-end terminal tripping consistent with zonal backup protection). The SDT believed the existing defined terms Normal Clearing and Delayed Fault Clearing were appropriate for the revised Table 1 Planning Event P5, as well as the revised Table 1 Footnote 13.

Clarification: What is the difference between a top-down versus bottom-up approach to Category P5 Events?

As part of simulating and analyzing results of P5 Event assessments, two common approaches to the Stability portion of simulations may be appropriate for planning entities to undertake. The first, referred to as the top-down approach, may initially focus upon determining critical clearing times for an entity's System topology given SLG faults. Once critical clearing times are obtained, the planning entity has the opportunity to collaborate with System Protection personnel to assess whether the installed Protection System may achieve the required performance. An advantage of the top-down approach is that the analytical burden to determine critical clearing times is front-loaded upon the planning entity and specific details regarding the Protection System are unnecessary prior to executing dynamics simulations. Conversely, the bottom-up approach may commence by the planning entity requesting the detailed causality and clearing times for SPF on the Protection System from Protection System personnel, requiring an extensive review of installed Protection Systems at the outset. While this approach may delay the execution of P5 Event studies, it may eliminate System topology that is not susceptible to SPF on the Protection System based upon Protection System personnel input and reduces the planning entity's dynamics simulation burden. Whether utilizing a top-down, bottom-up, combination of the two, or any other appropriate approach, the obligation specified in Table 1, Footnote 13 is for the planning entity to consider the non-redundant components of a Protection System that may lead to Delayed Fault Clearing when simulating the P5 Event.

Clarification: Is backup protection redundant?

The majority of BES Protection Systems are designed with overlapping zonal protection, including backup systems which eventually clear a fault in the event of a failure of the Protection System which is designed for Normal Clearing. Backup Protection Systems are not redundant for purposes of TPL-001-5 Table 1, Category P5 Events because they result in Delayed Fault Clearing and/or trip more Elements than the primary Protection System designed for Normal Clearing. Where the Protection System is designed with backup protections, the backup protection clearing time for a SLG fault must be the same as the clearing time for the primary Protection System designed for Normal Clearing, and must trip identical Elements, in order for the backup Protection System to be considered redundant to the primary Protection System. The SDT expects this type of design to be rare in its implementation, and correspondingly, backup protection is not considered redundant.

Table 1, Footnote 13

Footnote 13 is included in the TPL-001-5 Reliability Standard for the purpose of focusing the Transmission Planner and Planning Coordinator consideration of non-redundant components of a Protection System that may, when they fail, lead to Delayed Fault Clearing of the SLG fault simulated as part of the P5 event.

The SPCS and SAMS report recommended replacing "relay" with "component of a Protection System" in the Table 1 P5 event and replace Footnote 13 in TPL-001-4 with the following alternate wording:

> The components from the definition of 'Protection System' for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

A factor that the SDT considered when seeking to translate the SPCS and SAMS recommendations into the proposed TPL-001-5 Table 1, Footnote 13 was the need for Planning Coordinators and Transmission Planners to collaborate with System Protection personnel. The SDT recognized that the planning entities do not always have enough information alone to consider Protection System modes of failure or Delayed Fault Clearing than may result. Likewise, the SPCS and SAMS recommendations were adapted to target the potential non-redundant components of a Protection System that may likely need System Protection personnel input when determining how study simulations, performed by the planning entity, should be executed. Based on discussion and industry comment, the SDT revised Footnote 13 to clarify the components of the Protection System that must be considered when simulating Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System. This consideration is intended to account for:

- failed non-redundant components of a Protection System that may impact one or more Protection Systems;
- the duration that faults remain energized until Delayed Fault Clearing, and;

- additional system equipment removed from service following fault clearing depending upon the specific failed non-redundant component of a Protection System.

The SPCS and SAMS report described voltage or current sensing devices as having a lower level of risk of failure to trip due to robustness and likelihood to actually cause tripping upon failure. Therefore, these components of a Protection System are omitted from Footnote 13. Similarly, control circuitry whose failure does not prevent Normal Clearing of a fault, such as reclosing circuitry and reclosing relays, is omitted from Footnote 13 consideration.

Clarification: Does Footnote 13 prescribe redundancy?

It is emphasized that Footnote 13 does not prescribe any level of redundancy; on the contrary, Footnote 13 gives those non-redundant components of a Protection System that shall be considered for simulation of the Table 1 Planning Event P5 and Table 1 Extreme Events Stability column 2e-2h. Further, it is the Table 1 Planning Event P5 which prescribes the required System performance. The consideration of non-redundant components of a Protection System is necessary to properly simulate the Table 1 Planning Event P5 for the purpose of assessing whether required System performance is achieved. If, after proper consideration and simulation, required System performance is achieved, then there may be no impetus to make non-redundant components of a Protection System redundant. On the other hand, after proper consideration and simulation it is demonstrated that required System performance is not achieved, making non-redundant components of a Protection System redundant may be but one of many alternatives for corrective actions to obtain required System performance.

Clarification: Why is monitored and reported to a Control Center used in parts of Footnote 13?

The SDT recognized that some components of a Protection System may be monitored and their integrity reported to a Control Center. Different than an indication of a component failure that may be displayed in a remote site or in a location that may go unnoticed for a period, reporting to a Control Center implies that an unsatisfactory condition would be identified and corrective action be directed in short order. It is noted that short order is consistent with the “within 24 hours of detecting an abnormal condition” recommendation of the SPCS/SAMS report. Given that a risk-based approach to non-redundant components of a Protection System is appropriate, the SDT believed that components that may be SPF but are monitored and reported to a Control Center exhibited lower risk on par with being redundant, and therefore did not warrant P5 Event simulation.

Clarification: Why are relays that respond to electrical quantities addressed?

Noting that Requirement R3, Part 3.3.1 and Requirement R4, Part 4.3.1 require simulation of Protection System action, the SDT sought to limit the scope of Footnote 13a with respect to protective relays that may be non-redundant components of a Protection System. Specifically, Footnote 13 limits single protective relays that may be a SPF to those which respond to electrical quantities and are used for primary protection resulting in Normal Clearing. A SPF in a single protective relay that is a non-redundant component of a Protection System may result in the primary Protection System failing to properly operate, leading to Delayed Fault Clearing performed by backup protective relays and/or overlapping zonal protection. Conversely, the SDT did not include backup protective relays in the scope of Footnote 13a given that a SPF in a single protective relay used for backup protection will not affect primary protection resulting in Normal Clearing.

The SDT recognized that BES Elements are predominantly protected by relays which respond to electrical quantities. However, in some Protection System designs, non-redundant single protective relays which respond to electrical quantities may be redundant to protective relays that do not respond to electrical quantities. For example, an independent differential relay and independent sudden pressure relay may protect the same transformer from faults inside the transformer tank. In this example, the differential relay responds to electrical quantities, while the sudden pressure relay does not. While the transformer differential relay may be a SPF, an internal transformer tank fault may not lead to Delayed Fault Clearing given the sudden pressure protection, provided, in this example, that the resulting clearing time is similar to that achieved with the differential relay. Subsequently, the P5 event, for a single phase-to-ground (line-to-ground) fault in the transformer tank need not be simulated for Delayed Fault Clearing due to the SPF of the transformer differential relay if the resulting clearing time is similar to that achieved with the differential relay. However, care must be taken when evaluating protective relays which respond to electrical quantities in combination with protective relays which do not respond to electrical quantities; in this same example, faults that occurred outside of the transformer tank given the SPF of the non-redundant transformer differential relay would be unaffected by the presence of the sudden pressure relay and would lead to delayed clearing, necessitating its assessment as a P5 event (See Figure 1 and 2).

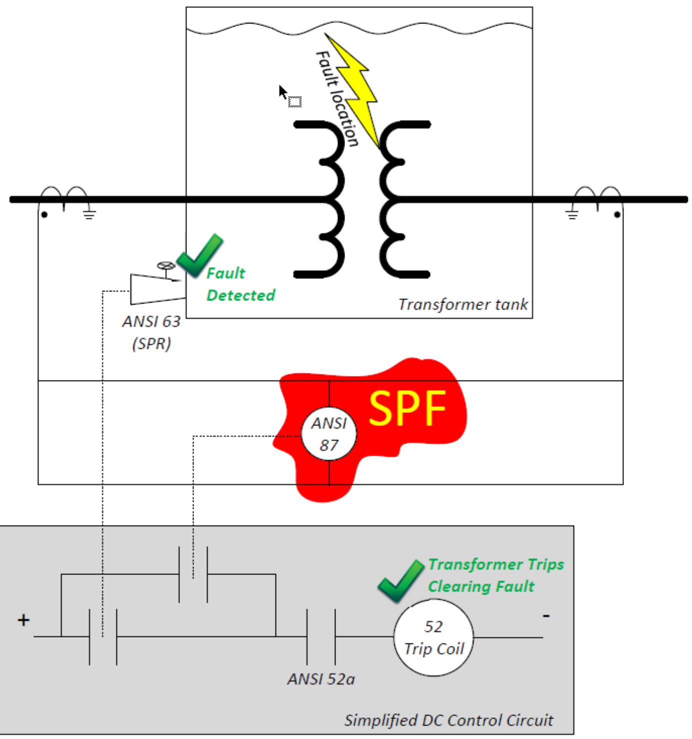

Figure 1: Internal Transformer Tank Fault with Sudden Pressure Protection and failed Transformer Differential Relay

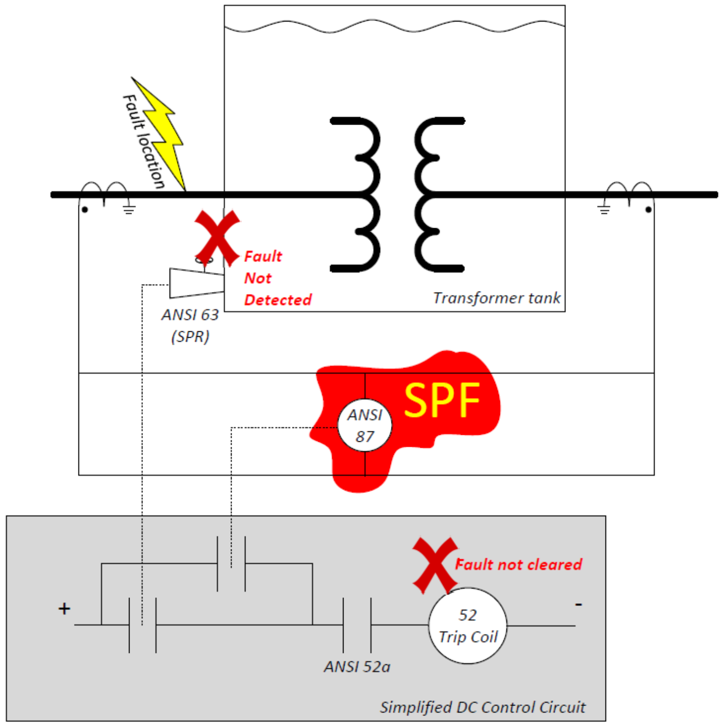

Figure 2: External Transformer Tank Fault with Sudden Pressure Protection and failed Transformer Differential Relay

Clarification: What is comparable and what is not comparable for purposes of footnote 13?

The use of "comparable" in Table 1, Footnote 13a applies only to alternatives for a single protective relay that responds to electrical quantities. For an alternative to be comparable to a single protective relay that responds to electrical quantities, the alternative must operate as designed to clear the fault within the time period expected if the single protective relay (that is simulated to fail as a SPF) were to function properly. Clearly, any alternative to a single protective relay that responds to electrical quantities may result in a different Element tripping sequence, leading to a different System topology after fault clearing which must be considered. Therefore, a comparable alternative to a single protective relay that responds to electrical quantities must result in fault clearing within the expected Normal Clearing time period and isolate the fault by tripping similar System Elements.

Clarification: Are separate Normal Clearing times comparable?

The SDT cannot anticipate all Protection System designs. However, the SDT's intent for alternatives to a single protective relay that responds to electrical quantities is implicit in the principle of comparable Normal Clearing times. In some cases, multiple layers of protection may overlap towards achieving a common System protective objective: to provide Normal Clearing. Examination of this design towards the common objective may indicate the Normal Clearing times are comparable. An example of this type of design may be a piloted relay for high-speed fault clearing used in conjunction with a non-piloted relay for primary or fast fault clearing. While these two relays may have different Normal Clearing times, their protective objective is common: to provide Normal Clearing. The clearing times of these two relays may be different, but are likely comparable. The applicable entity must understand the design of their own Protection System for the purpose of considering non-redundant components. Moreover, determination of whether alternatives, which may or may not respond to electrical quantities, provide comparable Normal Clearing times must be made with regard to the Protection System design, the expected fault clearing time, and the protective objective of its proper functioning.

Clarification: Why are communication-aided Protection Systems addressed?

Given the increasing importance of communication-aided Protection Systems (e.g., pilot protection schemes, direct transfer tripping schemes, permissive transfer tripping schemes, line differential relaying schemes, etc.), the proper operation of the communication system must be considered when considering potential SPF components of Protection Systems. The SDT augmented the SPCS/SAMS recommendations to include reference to the subset of communication systems that are part of a communication-aided Protection System, necessary where the performance of that Protection System is required to achieve Transmission System Planning (TPL) Performance Requirements, enumerated in Table 1 of TPL-001-4. In other words, a communication-aided Protection System that may experience a SPF, causing it to operate improperly or not at all, must be considered as part of non-redundancy. The SDT concluded that, although the failure of communication-aided Protection Systems may take many forms, by monitoring and reporting the status of these systems, the overall risk of impact to the BES can potentially be reduced to an acceptable level. However, monitoring and reporting the status of these systems can only really be considered as a sufficient alternative to physical redundancy if the result is prompt notification and remediation which minimizes the exposure to and consequence of this failed component. Most new Protection Systems deployed in the industry include communication-aided protection with component and communication failure alarms monitored at centralized Control Centers. Therefore, this requirement is more applicable to legacy systems that need communication-aided Protection Systems to meet performance requirements of the TPL standards.

Clarification: Why are DC supplies addressed?

The SDT adopted the fundamental principles of the SPCS/SAMS recommendations regarding station Protection System DC supply. Failure of a single station Protection System DC supply is a significant point of failure as it will prevent the operation of all local protection, including back-up protection. The SDT partly modified the SPCS/SAMS recommendation regarding single station DC supply, including removal of the specific requirement that reporting the detection of an abnormal condition to a location where corrective action can be initiated must occur within 24 hrs. This modification recognizes the wide variety of reporting and monitoring that exists. However, it remains the intention of Footnote 13c, that monitoring and reporting the status of the DC supply can only really be considered as a sufficient alternative to physical redundancy if the result is prompt notification and remediation which minimizes the exposure to and consequence of DC supply failure. Similar to as noted with communication-aided Protection Systems, most new Protection Systems include DC supply status alarms which are monitored at centralized Control Centers; however, they may not necessarily be monitored for both low voltage and open circuit. Therefore, this requirement may be more applicable to legacy systems.

Clarification: What differentiates a single station DC supply (Footnote 13c) from a single control circuitry (Footnote 13d)?

The station DC supply includes station battery, battery chargers and non-battery-based dc supply, as enumerated in the NERC Glossary of Terms definition of Protection System. The control circuitry includes everything from where the station DC supply terminates through and including the trip coils, including the wiring, as well as auxiliary and lockout relays. Further, the NERC Technical Paper *"Protection System Reliability Redundancy of Protection System Elements"* (November 2008) shows a demarcation between DC supply and the remainder of DC control circuitry. The SAMS and SPCS report and recommendations align with Figure 5-12 from this technical paper, shown below as Figure 3.

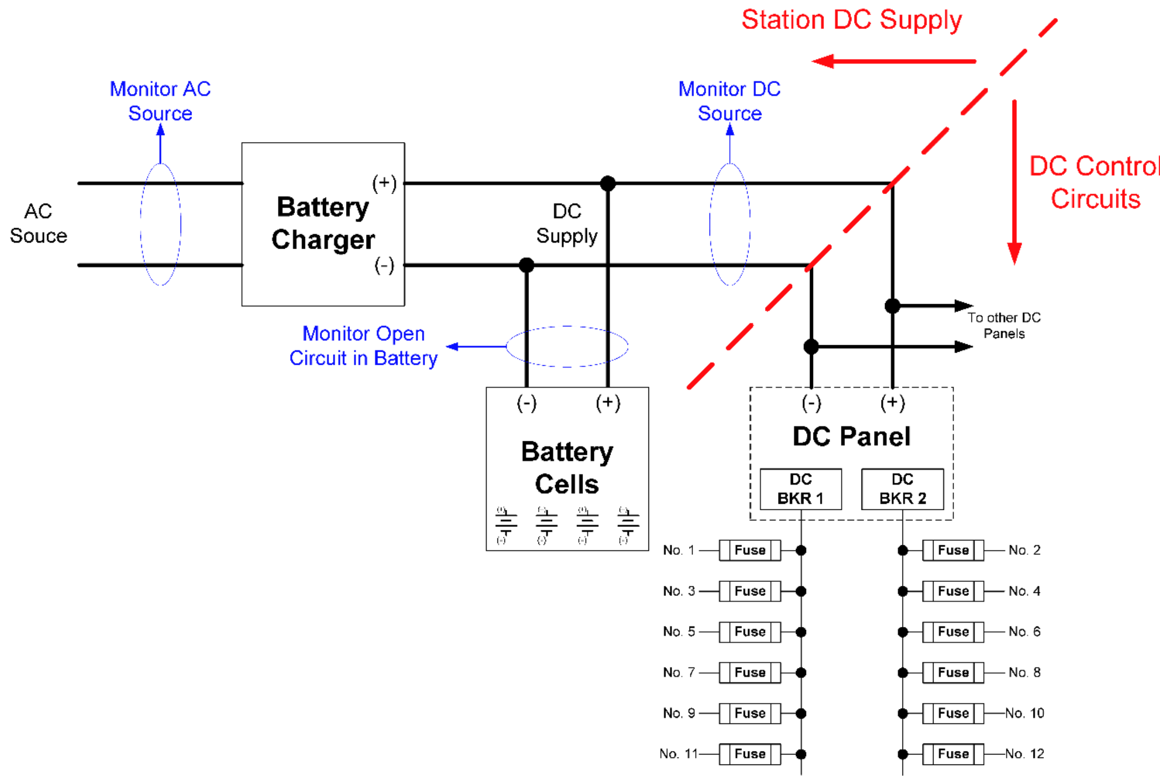

Figure 3 – Station DC supply and monitoring (Figure 5-2, from NERC Technical Paper "Protection System Reliability Redundancy of Protection System Elements", Nov 2008)

Simply monitoring for low voltage on the DC supply may omit situations where the DC supply voltage is satisfactory but the source path to DC control circuits may be open circuited. Thus, monitoring for low voltage and open circuit of the DC supply should be considered. Additionally, while the wiring in both the DC supply and the DC circuit have lower probabilities of failure as compared to other Protection System components, the SPCS and SAMS report identified this as a SPF risk.

Clarification: Is a battery charging system appropriate redundancy for the battery?
Battery chargers may not be of sufficient power to source current necessary to operate one or more breakers. For example, it is unlikely that a battery charger without a station battery in parallel would be capable of opening several breakers when demanded by a bus differential Protection System operation. Therefore, a battery charger cannot take the place of a redundant battery DC supply.

Clarification: Why is control circuitry addressed?
The SDT adopted the fundamental principles of the SPCS/SAMS recommendations regarding Protection System DC control circuitry. Failure of a Protection System single control circuitry is a significant point of failure as it will prevent proper tripping and, depending upon its design and mode of failure, may also prevent the initiation of breaker failure protection. Breaker failure is addressed by the Table 1 Planning Event P4 and is discussed in the next section. Further, most, if not all, constituent parts of the control circuitry are generally unmonitored, may fail, and may remain undetected until periodic testing is conducted. This is particularly significant for non-redundant auxiliary relays or lockout relays within the control circuitry because they may be used for multiple functions, such as multiplexing trip signals for differential or breaker failure initiation. Single control circuitry should be considered a non-redundant component of a Protection System given that Delayed Fault Clearing, including significantly delayed remote end or backup clearing, is expected when the non-redundant auxiliary or lockout relay device within the single control circuitry fails.

The single control circuitry is demarcated from the DC supply through and including the trip coil(s) for the purpose of including all devices in the control circuitry which, if failed, may prevent proper Protection System action leading to Delayed Fault Clearing. Trip coils are commonly employed in pairs (dual) for the purpose of incorporating redundancy to actuate the tripping of a circuit breaker or other interrupting device. However, the SDT partly modified the SPCS/SAMS recommendation regarding single control circuitry recognizing that some Protection System designs include a single trip instead of dual trip coils. When a single trip coil is employed, monitoring and reporting the status of the single trip coil can be considered as a sufficient alternative to its physical redundancy given that prompt notification and remediation is expected which minimizes the risk the trip coil failure. However, the trip coil(s), whether implemented singly or in pairs, are only part of the single control circuit; all its constituent parts should be included when considering whether the single control circuit may be a non-redundant component of a Protection System.

The Distinction between Category P4 and Category P5 Planning Events

"Table 1 – Steady State and Stability Performance Planning Events," makes a clear distinction between breaker failure, Category P4 Planning Events, and failure of a non-redundant component of a Protection System, Category P5 Planning Events. The sequence and timing of Protection System action leading to Delayed Fault Clearing may be quite different between the two fundamentally different causalities. Category P4 events involving the failure specifically of a circuit breaker assume that only the circuit breaker has failed, and that all other protection functions, including proper initiation of local breaker failure operation, has occurred correctly. For Category P5 Planning Events, failure of the various non-redundant components of a Protection System, as enumerated in Table 1, Footnote 13, can result in a relatively broader range of final system states, resulting from the Delayed Fault Clearing associated with the specific SPF, and which may or may not resemble the system states resulting from Delayed Fault Clearing associated with circuit breaker failure. Likewise, the Delayed Fault Clearing time that results from a Category P5 Event may be significantly longer that that expected when simulating Category P4 Event.

It is noted that there may be many instances where a fault followed by a breaker failure results in the exact same study simulations as a fault followed by a failure of a non-redundant component of a Protection System. There could be slight differences in clearing times and the Planning Coordinator or Transmission Planner may choose to simulate a P4 and P5 as one study using the longest expected clearing time. However**,** in the event of a bus fault followed by a bus differential protection failure, there may be a single relay (ANSI device 86) communicating to several breakers attached to the faulted bus. A bus fault on a breaker and a half configuration or double breaker double bus configuration may be particularly problematic in this case. For the Category P5 Event simulating this type of Protection System failure, none of the breakers which should open to clear the fault will receive the appropriate signal from the failed SPF relay and will not clear the bus fault. This makes the bus differential P5 Event significantly more severe than the P4 Event. The FERC Order 754 Section 1600 Data Request was specific to bus faults followed by a SPF of the Protection System.

In some cases, a P4 Event simulation at a specific location will be the same as the P5 Event simulation. For example: the failure of a control circuitry associated with a breaker trip coil results in the same analysis as the P4 for the breaker failing to open to clear a fault. Therefore, the P4 Event and the P5 Event may simulate the identical causality. However, if this simulation results in a performance requirement violation, the CAP must include mitigations for the P4 Event as well the P5 Event.

Extreme Events 2e-2h listed from the stability column of Table 1

Analysis of the data collected under the FERC Order No. 754 Section 1600 Data Request demonstrates the existence of a reliability risk associated with SPF in Protection Systems. Further, while the analysis shows that the risk from SPF is not an endemic problem and instances of SPF exposure are lower on higher voltage systems, the risk is sufficient to warrant further consideration. Risk-based assessment should be used to identify Protection Systems of concern (i.e., locations on the BES where there is a susceptibility to cascading if a Protection System component SPF exists). Given the risk to BES reliability, additional emphasis should be placed on assessment of three-phase faults involving a SPF on the Protection System. This concern, made manifest through the study of a three-phase fault and a SPF on a Protection System, is appropriately addressed as an extreme event in TPL-001-5, Requirement R4, Part 4.2. While less probable than SLG faults, three-phase faults frequently initiate as single-phase-to-ground with Delayed Fault Clearing and often evolve into three-phase faults, leading to Delayed Fault Clearing scenarios more severe than the Table 1, Category P5 Event. TPL-001-5, Requirement R4, Part 4.2, specifies that an evaluation of possible mitigating actions be conducted if analysis concludes there is cascading caused by the occurrence of extreme events. Thus, the SDT has maintained the three-phase-fault given a Protection System component SPF as an extreme event, but encourages consideration of implementing mitigating actions if it is cost-effective to do so.

Requirement R3, Parts 3.2 and 3.5 and Requirement R4, Parts 4.2 and 4.5

The SDT proposes non-substantive editorial changes to combine part of Requirement R3, Part 3.5 with Requirement R3, Part 3.2. The rearrangement of Requirement 3, Parts 3.2 and 3.5 were done to improve consistency within the Standard and do not create any new requirements. This is also true for Requirement R4, Part 4.2 and 4.5. However, it should be noted that the evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the (extreme) event is intended to support and encourage the implementation of reasonable, cost-effective measures to lessen the risk or severity of these events.

Section 2: FERC Order No. 786 Directives

Background

In addition to addressing reliability issues involving SPF on Protection Systems, proposed Reliability Standard TPL-001-5 revises the TPL-001 standard to address two directives from FERC Order No. 786.

FERC Order No. 786 P. 40: Maintenance outages in the Planning Horizon

FERC Order No. 786, Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments. Order No. 786 provides the following considerations:

- Planned maintenance outages less than six months may result in impacts during peak and off-peak periods;
- Planned outages during those times should be considered to allow for a single element to be taken out of service without compromising the ability to meet demand;
- Criticality of elements taken out for maintenance could result in N-1 outage and loss of non-consequential load or impact to reliability;
- Planned outages are not “hypothetical outages” and should not be treated as multiple contingencies in the planning standard (should be addressed in N-0 base case);
- Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages;
- The Near-Term Transmission Planning Horizon requires annual assessments using Year One or year two and year five. Known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon.

NERC SAMS Whitepaper Recommendations

To address this directive, the NERC SAMS recommended modifications to NERC Reliability Standards IRO-017-1 and TPL-001-4. The SAMS recommended that IRO-017-1 be used as the vehicle to assure that all types of known scheduled outages are being reviewed and coordinated to mitigate reliability impact as the most cost-effective means to address the intent of the NERC directive. The NERC SAMS also recommended modifying TPL-001-4, Requirement R1, Part 1.1.2 by removing “with duration of at least six months” and adding language referencing the outage coordination process developed in IRO-017-1, Requirement R1 as described above.

To understand the relationship between outage coordination and Transmission Planning Assessments, and how those relate to the FERC Order No. 786 directive and the current state of NERC Reliability Standards, SAMS considered the following:

- The duration of planned maintenance and construction outages can range from hours to many months or years. The impact that these outages can have on reliable operation of the BPS are irrespective of the duration of these outages, depending on many factors.
- Longer-term assessment of short-term outages or even longer-term outages is often considered an “academic exercise” due to concurrent outages, outage coordination practices and procedures, outage rescheduling and redesign, and alternative outage methods.
- The directives in FERC Order No. 786 pre-date the development of IRO-017-1, which was developed specifically to recognize the importance of outage coordination.
- Regional differences result in different outage coordination methods and procedures.

Revisions to TPL-001-4

Requirement R2, Parts 2.1.4 and 2.4.4

The SDT gave due consideration to the NERC SAMS recommendations and to a range of opinions and options regarding how to determine which known outages to include in the Near-Term Planning Assessment, which included varying, and sometimes conflicting, perspectives, such as that:

- the RC should not be consulted or involved at all in Planning Assessments,
- it is reasonable, appropriate, and efficient to consult with the RC,
- IRO-017 is adequate and applicable as it exists or with some modification, or
- maintenance outage selection for planning purposes should be at the sole discretion of the Transmission Planner or Planning Coordinator.

The range of these options reflects, in part, the substantial regional differences in outage coordination methods and procedures to address these types of outages. Those differences contribute to a legitimate difficulty in designing a reasonable and cost-effective continent wide means of addressing the FERC directive. However, FERC Order No. 786 requires that the issue be addressed. The rationale for selecting the known outages to be studied must be well thought out and available. The proposed modification is for consideration of known outages beyond, and therefore outside of, the Operations Planning time horizon.

The most prominent change the SDT proposes to address the FERC directive was to migrate the assessment of known outages from Requirement R1, which requires that System models shall represent, to Requirement R2, Parts 2.1 and 2.4 which requires how analyses shall be assessed and supported by studies. The SDT believed that this proposed change to where the assessment of known outages is specified in the TPL-001-5 requirements better aligns the approach necessary for the planning entities to execute their annual Planning Assessments.

The SDT modified Requirement R2, Part 2.1.4 and 2.4.4 consistent with FERC's directive, eliminating the specified six month outage duration and recognizing the various means that Planning Coordinators and Transmission Planners currently employ to consider the maintenance outages of concern, while meeting the requirements of Order No. 786. The proposed modifications place limitations on the known outages that need to be considered. The Planning Coordinator and Transmission Planner must have either a documented outage coordination procedure or technical rationale to select which known outages shall be assessed. The documented outage coordination procedure is intended to include consultation with the affected Reliability Coordinator, consultation with Transmission and/or Generator Owner(s) affected by the known outage, or application of documented outage coordination processes. The technical rationale is intended to include well-reasoned technical bases for making the determination. Consistent with the intention of Order No. 786, the SDT included the specification that the limitation of known outages to be modeled cannot be based solely on the outage duration. However, the presence of other accompanying factors, which in conjunction with outage duration, may form a reasonable basis for supporting that the known outage need not be assessed. It is only necessary to consider known outages expected to cause more severe System impacts, such as those that may result in Non-Consequential Load Loss for P1 event in Table 1. This allows the Planning Coordinator and Transmission Planner to use applicable means to assess which known outages are significant and prevents the need for conducting unnecessary assessment of outages which the Planning Coordinator and Transmission Planner do not expect to be problematic. The System conditions, such as peak or Off-Peak, that are expected during the period when the known outage is planned further limits the "non-hypothetical" analyses that may be performed. While it is inappropriate to assume that all known outages simulated in conjunction with Category P0 or P1 Events are identical to Category P3 or P6 Events, past or current studies may support the selection of known outage(s), if the study(s) has comparable post-Contingency System conditions and configuration such as those following P3 or P6 category events in Table 1 . However, it is imperative for the Planning Coordinator or Transmission Planner to document the justification for

supporting the known outage exclusion based upon past or current studies and why the post-Contingency System conditions and configuration are comparable in their technical rationale.

Clarification: Does TPL-001-5 duplicate requirements of IRO-017-1 for outage coordination?

The SDT was concerned that in order for the Planning Coordinator and Transmission Planner to jointly develop solutions with its respective Reliability Coordinator(s) for identified issues or conflicts with planned outages in its Planning Assessment for the Near-Term Transmission Planning Horizon, it must first assess the known outages as part of that Planning Assessment. However, if the Planning Coordinator or Transmission Planner does not know what outages to study, clearly outages may be omitted from having the opportunity for jointly developed solutions with the Reliability Coordinator, required in IRO-017-1. The SDT believed that the feedback loop between the planning entities and the Reliability Coordinator ends with the planning entities presenting their study results in the Planning Assessment, but must begin with strong collaboration and sourcing of information regarding known outages that should be studied beyond the Operations Horizon by the Reliability Coordinator. Therefore, the SDT does not believe that there is duplication between the proposed TPL-001-5 and IRO-017-1 standards. Moreover, the SDT believes there is an implied need to strengthen the collaboration and consultation between the Reliability Coordinator and the planning entities at the outset of determining the known outages that should be assessed in the Near-Term Transmission Planning Horizon.

FERC Order No. 786 P 89: Dynamic assessment of outages of critical long lead time equipment

In paragraph 89 of Order No. 786, FERC stated:

> The spare equipment strategy for steady state analysis under Reliability Standard TPL-001-4, Requirement R2, Part 2.1.5 requires that steady state studies be performed for the P0, P1 and P2 categories identified in Table 1 with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment. The Commission believes that a similar spare equipment strategy for stability analysis should exist that requires studies to be performed for P0, P1 and P2 categories with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment.

FERC did not direct a change but did direct NERC to consider this issue upon the next review cycle of TPL-001-4. The Project 2015-10 Standard Authorization Request included this issue within the scope of this project.

Clarification: Does TPL-001-5 prescribe an entity's spare equipment strategy?

No. The SDT addressed the guidance in paragraph 89 of Order No. 786 regarding stability analysis to assess System performance for conditions expected during possible unavailability of long lead time equipment in TPL-001-5 Requirement R2, Part R2.4.5. The SDT recognized that "spare equipment strategy" is not a NERC-defined term and believed it was sufficient to allow flexibility for applicable entities to conduct both steady state and stability analysis required by TPL-001-5 Requirement R2, Parts R2.1.5 and R2.4.5. For example, an entity's spare equipment strategy may include the warehousing of a replacement transformer to be installed given the failure of an in-service BES transformer. When an entity's spare equipment strategy may prevent major Transmission equipment from being out-of-service for one year or more, this possible equipment unavailability need not be assessed as part of TPL-001-5 Requirement R2, Parts R2.1.5 and R2.4.5.

NERC SAMS Whitepaper Recommendations

The NERC SAMS considered the following key points related to FERC's Paragraph 89 guidance:

- Removal of Elements in the Planning Assessment for spare equipment strategy is only applicable for those Elements that have “a lead time of one year or more.”
- Each long-lead time Element that is removed from service creates a new operating condition considered the “normal” (P0) condition for Table 1. The applicable contingencies will be studied with that Element removed from service in the pre-contingency state for stability analysis. For example, if a long-lead time transformer does not have a spare, it would be studied as a P1.3 event. Since P0 does not include an Event, P0 does not and should not be included in the stability analysis section for long-lead time Elements not included as part of a spare equipment strategy.
- System adjustments may need to be made to the power flow base case to accurately reflect reasonable and expected operating conditions with that Element removed from service in the pre-contingency (P0) operating state.
- TPL-001-4, Requirement R4, Part4.1.1, related to P1 Events, requires that no generating unit pull out of synchronism. The outage of a long-lead time Element followed by a P1 contingency should not result in a generating unit losing synchronism.
- TPL-001-4, Requirement R4, Part 4.1.2, related to P2 Events, allows for generating units to pull out of synchronism. The outage of a long-lead time Element followed by a P2 contingency should not result in tripping of any Transmission System Elements other than the generating unit and its directly connected Facilities.

The NERC SAMS white paper contains the flowing recommendations for stability analysis for long lead time Elements not included as part of a spare equipment strategy:

- The outage of long lead time Elements has an equally important impact from a stability standpoint as it does from a steady-state standpoint.
- The Planning Coordinator and Transmission Planner must demonstrate that they have met the TPL-001-4 performance criteria for specified contingency events and contingency combinations thereof as per Table 1. This should include long lead time outages that can occur for equipment that does not have a spare equipment strategy.
- TPL-001-4, Requirement R4, Part4.1.1 requires that no generating unit pull out of synchronism, while R4.1.2 allows for generating units to pull out of synchronism so long as the resulting instability does not result in tripping of any Transmission System Elements other than the generating unit and its directly connected Facilities. The outage of a long lead time Element followed by a P1 contingency should not result in a generating unit losing synchronism.
- While the P2 contingency allows for individual generating unit instability, the Transmission Planner and Planning Coordinator must ensure that this instability does not result in tripping of any Transmission System Elements other than the generating unit and its directly connected Facilities and therefore should include P2 contingencies event.

Revisions to TPL-001-4

Requirement R2, Part 2.4.5

Consistent with FERC’s Order No. 786 guidance and the SAMS recommendations, the Project 2015-10 SDT revised TPL-001-4 Requirement R2, Part 2.4.5 to add a similar requirement for stability analysis. The change to Requirement R2, Part 2.4.5, which includes similar language to that used for the steady-state analysis under Requirement R2, Part 2.1.5, adds clarity that the outage of long lead time Elements has an equally important impact from a stability standpoint as it does from a steady-state standpoint and should be assessed commensurate with an entity’s spare equipment strategy.

Section 3: Applicability

The requirements remain applicable to the Planning Coordinator and Transmission Planner. Coordination and cooperation between operating and planning entities in concert with asset owners will be required to implement the standard requirements. The planning entities and System Protection personnel that will need to collaborate when conducting the studies and submitting the data may be working for different companies or business units, and time will be required to accommodate the development of processes and data flow that cross company or business unit lines. Coordination with Generator Owners, Transmission Owners, and Distribution Providers will be necessary to evaluate the Protection System(s) for locations on the system where a failure of a non-redundant component of a Protection System could result in a potential reliability risk. Transmission Planners and Planning Coordinators must obtain this information, as well as resulting fault clearing times, to perform proper studies.

Summary of Development

and

Complete Record of Development

Summary of Development History

Summary of Development History

The development record for proposed Reliability Standard TPL-001-5 is summarized below.

I. Overview of the Standard Drafting Team

When evaluating a proposed Reliability Standard, the Commission is expected to give "due weight" to the technical expertise of the ERO.[1] The technical expertise of the ERO is derived from the standard drafting team selected to lead each project in accordance with Section 4.3 of the NERC Standards Process Manual.[2] For this project, the standard drafting team consisted of industry experts, all with a diverse set of experiences. A roster of the standard drafting team ("SDT") members is included in **Exhibit H**.

II. Standard Development History

A. Standard Authorization Request Development

Project 2015-10 – Single Points of Failure TPL-001 was initiated in 2015 following the submission of a Standards Authorization Request ("SAR") to address findings and recommendations from a report prepared by the NERC System Protection and Control Subcommittee and System Modeling and Analysis Subcommittee on Protection System single points of failure. The SAR was initially posted for a 30-day informal comment period from November 12, 2015 through December 17, 2015. The SAR was subsequently expanded to address the outstanding FERC directives from Order No. 786 and to update the MOD references in the TPL standard. The revised SAR was posted for an additional 30-day informal comment

1 Section 215(d)(2) of the Federal Power Act; 16 U.S.C. §824(d)(2) (2012).
2 The NERC *Standard Processes Manual* is available at http://www.nerc.com/comm/SC/Documents/Appendix_3A_StandardsProcessesManual.pdf.

period from May 26, 2016, through June 24, 2016. The SAR was accepted by the SC on July 20, 2016.

B. First Posting – Informal Comment Period

Proposed Reliability Standard TPL-001-5 was posted for a 30-day informal comment period from April 25, 2017 through May 24, 2017. There were 63 sets of responses, including comments from approximately 180 different individuals and approximately 129 companies representing all 10 industry segments.[3]

C. Second Draft – Comment Period, Initial Ballot, and Non-binding Poll

Proposed Reliability Standard TPL-001-5 and the associated Violation Risk Factors ("VRFs"), and Violation Severity Levels ("VSLs") were posted for a 45-day formal comment period from September 8, 2017 through October 23, 2017, with parallel initial ballot and non-binding poll held during the last 10 days of the comment period from October 13, 2017 through October 23, 2017. The initial ballot received a 30.5% industry approval with a quorum of 82.99%. The related non-binding poll received a 31.03% industry approval with a quorum of 79.56%. There were 70 sets of responses, including comments from approximately 192 different individuals and approximately 118 companies, representing all 10 industry segments.[4]

D. Third Draft – Comment Period, Additional Ballot, Non-binding Poll and Implementation Plan Initial Ballot

Proposed Reliability Standard TPL-001-5 was posted for a second 45-day formal comment period and additional ballot from February 23, 2018 through April 23, 2018.[5] A parallel initial ballot for the Implementation Plan and a non-binding poll of the associated VRFs and VSLs held during the last 10 days of the comment period from April 13, 2018 through April 23, 2018. The additional ballot for TPL-001-5 received a 26.44% industry approval with a quorum of 80.27%. The related non-binding poll for the associated VRFs and VSLs received a 27.01% industry approval with a quorum of 76.28%. The initial ballot for the Implementation Plan received a 41.13% industry approval with a quorum of 78.23%. There were 70 sets of responses, including comments from approximately 190 different individuals and approximately 117 companies, representing all 10 industry segments.[6]

E. Fourth Draft – Comment Period, Additional Ballot and Non-binding Poll

Proposed Reliability Standard TPL-001-5 was posted for a third 45-day formal comment period and additional ballot from July 30, 2018 through September 14, 2018,. A parallel additional ballot for the Implementation Plan and a non-binding poll of the associated VRFs and VSLs were held during the last 10 days of the comment period from September 5, 2018 through September 14, 2018. The additional ballot for TPL-001-5 received a 69.07% industry approval with a quorum of 75.85%. The additional ballot for the proposed Implementation Plan received a 73.27% industry approval with a quorum of 75.51%. The related non-binding poll for the associated VRFs and VSLs received a 68.64% industry approval with a quorum of 78.47%.

---

5 The comment period for this posting, which was initially scheduled to close on April 9, 2018, was extended to April 23, 2018 following the posting of updated documents on March 8, 2018. The ballot dates were adjusted accordingly.

6 NERC, *Consideration of Comments*, Project 2015-10 – Single Points of Failure | TPL-001-5, (July 2018), *available at* https://www.nerc.com/pa/Stand/Project_201510%20Single%20Points%20of%20Failure_TPL001_DL/2015-10_TPL-001-5_Consideration_of_Comments_07302018.pdf.

There were 51 sets of responses, including comments from approximately 148 different individuals and approximately 96 companies, representing all 10 industry segments.[7]

F. Final Ballot

Proposed Reliability Standard TPL-001-5 and the Implementation Plan were posted for a 10-day final ballot period from October 11, 2018 through October 22, 2018. The proposed standard received a 66.69% industry approval with a quorum of 86.39%. The proposed Implementation Plan received a 72.44% industry approval with a quorum of 86.73%.

G. Board of Trustees Approval

Proposed Reliability Standard TPL-001-5, the Implementation Plan, and the associated VRFs and VSLs were adopted by the NERC Board of Trustees on November 7, 2018.[8]

Status
The final ballots for **TPL-001-5 – Transmission System Planning Performance Requirements** and the **implementation plan,** concluded **8 p.m. Eastern, Monday, October 22, 2018**. The voting results can be accessed via the links below. The standard and implementation plan will be submitted to the Board of Trustees for adoption and then filed with the appropriate regulatory authorities.

Background
The SPCS and the SAMS conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action**.**

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Standard(s) Affected: TPL-001-4 - Transmission System Planning Performance Requirements

Purpose/Industry Need
The proposed standard project will benefit reliability by providing clear, unambiguous and results-based reliability standard requirements to address the assessment's recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request."

Unoffical Nomination Form

Project 2015-10 Single Points of Failure – TPL-001 Standards Authorization Request Drafting Team

Do not use this form for submitting nominations. Use the electronic form to submit nominations by **8 p.m. Eastern, Tuesday, December 1, 2015.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Documents and information about this project are available on the project page. If you have any questions, contact Standards Developer, Katherine Street (via email) or at (404) 446-9702.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in the review or drafting team meetings if appointed by the Standards Committee. If appointed, you are expected to attend most of the face-to-face drafting team meetings, as well as participate in all the team meetings held via conference calls.

The time commitment for these projects is expected to be up to two face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the review or drafting team sets forth. Drafting teams also will have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the review and drafting team efforts is outreach. Members of the team should be conducting outreach during development prior to posting to ensure all issues can be discussed and resolved.

Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Project 2015-10 Single Points of Failure

The purpose of the proposed project is to draft a Standards Authorization Request (SAR) to address the findings of the System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) assessment of protection system single points of failure, conducted in response to FERC Order No. 754,[1] including analysis of data from the NERC Rules of Procedure Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.

[1] In Order No. 754, the Commission expressed its concern that there was an issue concerning the study of a single point of failure on protection systems. To address this issue, the Commission directed FERC staff to meet with NERC and its appropriate subject matter experts to explore this reliability concern. The Commission also directed NERC to submit an informational filing within six months explaining whether there is a further system protection issue that needs to be addressed and if so, what forum and process should be used to address it and what priority it should be afforded. *See Interpretation of Transmission Planning Reliability Standard*, Order No. 754, 136 FERC ¶ 61,186 at PP 19-20 (2011).

As such, regarding single points of failure in protection systems, the SPCS and the SAMS proposed the following recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process identified in the NERC Rules of Procedure:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace "relay" with "component of a Protection System," and
  - Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase "or a relay failure" from items a, b, c, and d to create distinct events only for stuck breakers.
  - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure" with "a component failure of a Protection System."
- Replace footnote 13 in TPL-001-4 with, "The components from the definition of "Protection System" for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."[2]

Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

Standards affected: TPL-001-4

We are seeking a cross section of the industry to participate on the team, but in particular are seeking individuals who have experience and expertise with transmission planning in the United States and/or Canada.

Experience with developing standards inside or outside (e.g., IEEE, NAESB, ANSI, etc.) of the NERC process is beneficial, but is not required, and should be highlighted in the information submitted, if applicable.

Individuals who have facilitation skills and experience and/or legal or technical writing backgrounds are also strongly desired. Please include this in the description of qualifications as applicable.

Name:	
Organization:	

[2] See Order 754 (NERC website) Requests for Clarifications and Responses (http://www.nerc.com/pa/Stand/Order%20754%20DL/Order_754-Requests_for_Clarification_and_Responses_July2013.pdf).

Address:	
Telephone:	
E-mail:	

Please briefly describe your experience and qualifications to serve on the requested Standard Drafting Team (Bio):

If you are currently a member of any NERC drafting team, please list each team here:

☐ Not currently on any active SAR or standard drafting team.

☐ Currently a member of the following SAR or standard drafting team(s):

If you previously worked on any NERC drafting team please identify the team(s):

☐ No prior NERC SAR or standard drafting team.

☐ Prior experience on the following team(s):

Select each NERC Region in which you have experience relevant to the Project for which you are volunteering:

☐ TRE	☐ NPCC	☐ SPP
☐ FRCC	☐ RFC	☐ WECC
☐ MRO	☐ SERC	☐ NA – Not Applicable

Select each Industry Segment that you represent:

☐	1 — Transmission Owners
☐	2 — RTOs, ISOs
☐	3 — Load-serving Entities
☐	4 — Transmission-dependent Utilities
☐	5 — Electric Generators
☐	6 — Electricity Brokers, Aggregators, and Marketers
☐	7 — Large Electricity End Users
☐	8 — Small Electricity End Users

☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
☐	10 — Regional Reliability Organizations and Regional Entities
☐	NA – Not Applicable

Select each Function[3] in which you have current or prior expertise:

☐ Balancing Authority	☐ Transmission Operator
☐ Compliance Enforcement Authority	☐ Transmission Owner
☐ Distribution Provider	☐ Transmission Planner
☐ Generator Operator	☐ Transmission Service Provider
☐ Generator Owner	☐ Purchasing-selling Entity
☐ Interchange Authority	☐ Reliability Coordinator
☐ Load-serving Entity	☐ Reliability Assurer
☐ Market Operator	☐ Resource Planner
☐ Planning Coordinator	

Provide the names and contact information for two references who could attest to your technical qualifications and your ability to work well in a group:

Name:		Telephone:	
Organization:		E-mail:	
Name:		Telephone:	
Organization:		E-mail:	

[3] These functions are defined in the NERC Functional Model, which is available on the NERC web site.

Standards Announcement

Project 2015-10 Single Points of Failure
Standard Authorization Request (SAR)

SAR Drafting Team Nomination Period Open through December 1, 2015

Now Available

Nominations are being sought for SAR drafting team members through **8 p.m. Eastern, Tuesday, December 1, 2015**.

Use the electronic form to submit a nomination. If you experience any difficulties in using the electronic form, contact Wendy Muller. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies page and the project page.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in the drafting team meetings if appointed by the Standards Committee. If appointed, you are expected to attend most of the face-to-face team meetings, as well as participate in all the team meetings held via conference calls.

The time commitment for this project is expected to be up to two face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the team sets forth. Drafting teams also will have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the drafting team efforts is outreach. Members of the team should be conducting outreach during development prior to posting to ensure all issues can be discussed and resolved.

Previous drafting team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included on the project page and the nomination form.

Next Steps

The Standards Committee is expected to appoint members to the team in December 2015. Nominees will be notified shortly after they have been appointedt.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Standards Developer, Katherine Street (via email) or at (404) 446-9702.

☐ New Standard ☒ Revision to existing Standards		☐ Withdrawal of existing Standard ☐ Urgent Action	

SAR Information
Industry Need (What is the industry problem this request is trying to solve?):
The System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) conducted a comprehensive assessment of the study of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.

SAR Information

As such, regarding single points of failure in protection systems, the SPCS and the SAMS make the following recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process identified in the NERC Rules of Procedure:
 	
• For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
   ▪ Replace "relay" with "component of a Protection System," and
   ▪ Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
• For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
   ▪ Remove the phrase "or a relay failure[13]" from items a, b, c, and d to create distinct events only for stuck breakers.
   ▪ Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure[13]" with "a component failure of a Protection System[13]."
• Replace footnote 13 in TPL-001-4 with, "The components from the definition of "Protection System" for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."[1]
• Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

[1] See Order 754 (NERC website) Requests for Clarifications and Responses (http://www.nerc.com/pa/Stand/Order%20754%20DL/Order_754-Requests_for_Clarification_and_Responses_July2013.pdf).

SAR Information
Purpose or Goal (How does this request propose to address the problem described above?):
The primary goal of this SAR is to appoint a Standard Drafting Team (SDT) to address recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) as identified in the SPCS and SAMS report titled “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request.”
Identify the Objectives of the proposed standards’ requirements (What specific reliability deliverables are required to achieve the goal?):
Provide clear, unambiguous requirements and Results-based Reliability standards to address the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request.”
Brief Description (Provide a paragraph that describes the scope of this standard action.)
The SDT shall consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request,” and revise standards, requirements, attachments, Violation Risk Factors, Violation Severity Levels, and implementation plans as appropriate. The SDT shall consider retirements to requirements under Paragraph 81 criteria. In addition, the SDT shall work with compliance on an accompanying RSAW to address each of the standard’s requirements and measures.
Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR. Also provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)
The SDTs execution of this SAR requires the SDT to address the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request.” The SDTs execution of this SAR would, in addition, consider retirements to requirements under Paragraph 81 criteria. The SPCS and SAMS report titled “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request” is incorporated in its entirety into this SAR, so as not to unnecessarily repeat or paraphrase the substance report.

Reliability Functions		
The Standard will Apply to the Following Functions (Check each one that applies.)		
☐	Regional Reliability Organization	Conducts the regional activities related to planning and operations, and coordinates activities of Responsible Entities to secure the reliability of the Bulk Electric System within the region and adjacent regions.
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator’s wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☐	Transmission Owner	Owns and maintains transmission facilities.
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.

Reliability Functions		
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles	
Applicable Reliability Principles (Check all that apply).	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Reliability and Market Interface Principles	
Does the proposed Standard comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

Project 2015-10 Single Points of Failure – TPL-001

Do not use this form for submitting comments. Use the electronic form to submit comments on the **Project 2015-10 Single Points of Failure Standard Authorization Request (SAR)**. Comments must be submitted by **8 p.m. Eastern, Thursday, December 17, 2015**.

Documents and information about this project are available on the project page. If you have questions, contact Katherine Street (via email) or by telephone at (404)-446-9702.

Background Information

This posting is soliciting informal comment on the SAR.

The purpose of the proposed project is to draft a SAR to address the findings of the System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) assessment of protection system single points of failure, conducted in response to FERC Order No. 754,[1] including analysis of data from the NERC Rules of Procedure Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.

As such, regarding single points of failure in protection systems, the SPCS and the SAMS proposed the following recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process identified in the NERC Rules of Procedure:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace “relay” with “component of a Protection System,” and
  - Add superscript “13” to reference footnote 13 for the replaced term under the “Category” column.
- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase “or a relay failure” from items a, b, c, and d to create distinct events only for stuck breakers.

[1] In Order No. 754, the Commission expressed its concern that there was an issue concerning the study of a single point of failure on protection systems. To address this issue, the Commission directed FERC staff to meet with NERC and its appropriate subject matter experts to explore this reliability concern. The Commission also directed NERC to submit an informational filing within six months explaining whether there is a further system protection issue that needs to be addressed and if so, what forum and process should be used to address it and what priority it should be afforded. *See Interpretation of Transmission Planning Reliability Standard*, Order No. 754, 136 FERC ¶ 61,186 at PP 19-20 (2011).

    - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing “a relay failure” with “a component failure of a Protection System.”
- Replace footnote 13 in TPL-001-4 with, “The components from the definition of “Protection System” for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.”[2]
- Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads “[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2.”

Questions

1. Do you agree with the scope and objectives of the SAR? If not, please explain why you do not agree and, if possible, **provide specific language revisions that would make it acceptable to you**.

   ☐ Yes
   ☐ No
   Comments:

2. If you have any other comments on this SAR that you haven’t already mentioned above, please provide them here:

Table of Contents

Preface

The North American Electric Reliability Corporation (NERC) is a not-for-profit international regulatory authority whose mission is to ensure the reliability of the bulk power system (BPS) in North America. NERC develops and enforces NERC Reliability Standards;[1] annually assesses seasonal and long-term reliability; monitors the BPS through system awareness; and educates, trains, and certifies industry personnel. NERC's area of responsibility spans the continental United States, Canada, and the northern portion of Baja California, Mexico. NERC is the electric reliability organization (ERO) for North America, subject to oversight by the Federal Energy Regulatory Commission ("FERC" or "Commission") and governmental authorities in Canada. NERC's jurisdiction includes users, owners, and operators of the BPS, which serves more than 334 million people.

The North American BPS is divided into several assessment areas within the eight Regional Entity (RE) boundaries, as shown in the map and corresponding table below.

FRCC	Florida Reliability Coordinating Council
MRO	Midwest Reliability Organization
NPCC	Northeast Power Coordinating Council
RF	ReliabilityFirst
SERC	SERC Reliability Corporation
SPP RE	Southwest Power Pool Regional Entity
TRE	Texas Reliability Entity
WECC	Western Electricity Coordinating Council

[1] Capitalized terms include, but are not limited to the Glossary of Terms Used in NERC Reliability Standards. March 3, 2015. (http://www.nerc.com/pa/Stand/Glossary%20of%20Terms/Glossary_of_Terms.pdf) and Definitions Used in the NERC Rules of Procedure (ROP), Appendix 2. July 1, 2014. (http://www.nerc.com/FilingsOrders/us/RuleOfProcedureDL/Appendix_2_ROP_Definitions_20140701_updated_20140602.pdf).

Executive Summary

This report provides the results of an assessment of protection system single points of failure (SPF) in response to FERC Order No. 754,[2] including analysis of data from the NERC Section 1600 Request for Data or Information. Based on the analysis of data received, the report provides a discussion of alternatives to address this reliability concern and recommends a course of action to address the concern using a risk-based method.

Nearly 4,000 buses energized above 100kV were examined in detail. This is a comprehensive set of the key buses in the Bulk Electric System. This assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.

Regarding single points of failure in protection systems, the System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) considered a variety of alternatives, and concluded that the most appropriate recommendation that aligns with O754 directives and maximizes reliability of protection system performance is to modify NERC Reliability Standard TPL-001-4 (*Transmission System Planning Performance Requirements*) through the NERC standards development process defined in the NERC Rules of Procedure. The recommended modifications address specifics of Protection System component failure, aspects of steady state and stability performance testing, and expansion of extreme event assessment requirements in order to minimize the potential risk of SPFs. Chapter 2 contains a discussion of alternatives considered. Specific guidance for modifying NERC Reliability Standard TPL-001-4 is provided in Chapter 3.

[2] *Interpretation of Transmission Planning Reliability Standard*, Order No. 754, 136 FERC ¶ 61,186 (2011) ("Order No. 754") (http://www.ferc.gov/whats-new/comm-meet/2011/091511/E-4.pdf).

Introduction

Objective

The objective of this assessment is to determine whether there is a reliability concern that NERC should address regarding the study of single points of failure on protection systems and, if so, what forum and process should be used to address the issue. This report provides the results of a comprehensive assessment of the study of data from the NERC Section 1600 Request for Data or Information collected in response to FERC Order No. 754. Based on the analysis of data, there is some degree of elevated reliability risk from SPF in certain key instances. The report provides discussion of alternatives to address this reliability concern and recommends a course of action to address the concern using a risk-based method.

Background

The issue of protection system failures brought to the forefront potential reliability concerns in Requirement R1.3.10 of the NERC transmission planning Reliability Standard TPL-002-0b (*System Performance Following Loss of a Single Bulk Electric System Element (Category B)*). The concern relevant to this assessment is whether Requirement R1.3.10 requires the study of protection system failures as part of Category B disturbances.

In FERC Order No. 754, issued September 15, 2011, the Commission agreed with commenters that this issue does not have to be addressed in TPL-002-0b, Requirement R1.3.10. However, the Commission also stated their belief that there is "an issue concerning the study of the non-operation of non-redundant primary protection systems; e.g., the study of a single point of failure on protection systems."[3] To address this concern, the Commission directed FERC staff to meet with NERC and its appropriate subject matter experts to explore the reliability concern, including where it can best be addressed, and identify any additional actions necessary to address the matter.

To satisfy the directive, a FERC Technical Conference was held October 24–25, 2011, to facilitate an open exchange among FERC staff, NERC staff, and industry stakeholders. One outcome of the FERC Technical Conference was that NERC would conduct a data collection effort to provide a broad factual foundation that could aid in assessing whether single points of failure in protection systems pose a reliability concern. NERC staff worked with the SPCS and SAMS to develop a request for data or information under Section 1600 of the NERC Rules of Procedure[4] (the "Data Request" or "Order No. 754 Data Request"). The NERC Board of Trustees approved the Data Request on August 16, 2012.

The responsible Functional Entities ("entities") have submitted data to NERC for buses operated at 100 kV and above. Data is presented in Appendix A of this report according to voltage range (100–199 kV, 200–299 kV, 300–399 kV, 400–599 kV, and 600 kV or higher). The SPCS and SAMS have reviewed the submitted data, which provides statistical information on the number of buses at which a protection system single point of failure could result in an adverse impact to reliability of the bulk power system. The data also indicates the extent to which exposure to single points of failure exists at these buses, broken down by specific component categories of a protection system.

The assessment of this data set forms the basis for identifying the risk associated with protection system single points of failure, development of alternatives to address associated concerns, and subsequently a recommendation of the preferred alternatives to address the associated concerns.

Chapter 1 – Analysis of Data

Order No. 754 Data Request

Overview

The Order No. 754 Data Request[5] required that Transmission Planners, working with the Generator Owners, Transmission Owners, and Distribution Providers within their transmission planning areas, assess their portion of the Bulk Electric System (BES) for locations at which a three-phase fault accompanied by a protection system failure could result in a potential reliability risk. To accomplish this task in an effective and efficient manner, the SPCS and SAMS developed a method that entities could follow to create the statistics associated with this Data Request. Entities were permitted to use an alternate method, including combining steps, skipping steps, or reordering steps, to minimize burden based on their particular circumstances, and could use information from existing studies and existing assessments of protection systems in developing responses to the data request. For example, TPL-004-0a (*System Performance Following Extreme Events Resulting in the Loss of Two or More Bulk Electric System Elements (Category D)*) simulations from transmission planning assessments could be used in developing responses to the Data Request.

Entities that followed an alternate method or utilized existing studies and existing assessments of protection systems in developing responses were required to provide a complete subset of buses containing both of the following characteristics:

- The bus has at least one Element for which the protection system does not fully meet the redundancy attributes for all component categories of Table B (from the data request), "Protection System Attributes
- Planning studies simulating a three phase fault, show that clearing times resulting from a single point failure of at least one protection system on an Element connected to that bus will result in system performance exhibiting one of the adverse impacts identified in Table C (from the data request), "Performance Measures."

The process of using differing methodologies to obtain this list of buses results in inconsistencies in the specific numbers of Protection Systems and buses evaluated in the various tables of Protection System attributes.

The Data Request included criteria to limit the assessment to a sample of buses using qualitative criteria that identified and included the buses more likely to have a more significant stability impact on the bulk power system. See Table 1.1 below, which is Table A from the Data Request.

[5] Request for Data or Information: Order No. 754 Single Point of Failure on Protection Systems, August 16, 2012.

Table 1.1: Criteria for Buses to be Tested
Buses operated at 200 kV or higher with 4 or more circuits
Buses operated at 100 kV to 200 kV with 6 or more circuits
Buses operated at 100 kV or higher that directly supply off-site power to a nuclear generating station
Any additional buses operated at 100 kV or higher that the Transmission Planner believes are necessary for the reliable operation of the bulk power system

For the buses meeting the Table 1.1 criteria, the Transmission Planner assessed the system performance for a three-phase fault accompanied by a protection system failure. For the purposes of the Data Request, Transmission Planners were to simulate clearing, based on the remote protection that would operate for the bus fault. The Transmission Planners were not to simulate operation of any local protection with the exception of local breaker failure protection (where provided) in instances where a single trip coil was the only single point of failure for protection systems on all Elements connected to the bus. In these cases, operation of the breaker failure protection was allowed in the simulation.

Following simulation of the events described above, the Transmission Planner evaluated the system performance against criteria provided in the Data Request that the SPCS and SAMS believe are indicative of the potential for instability, uncontrolled separation, or cascading outages. The criteria are contained in Table 1.2 below, which is Table C from the Data Request.

Table 1.2: Performance Measures
1. Loss of synchronism of generating units totaling greater than 2,000 MW or more in the Eastern Interconnection or Western Interconnection, or 1,000 MW or more in the ERCOT or Québec Interconnections
2. Loss of synchronism between two portions of the system
3. Negatively damped oscillations

For buses where the simulated system performance exhibited one or more of the adverse system response characteristics in Table 1.2, the protection system owners (Generator Owners, Transmission Owners, and Distribution Providers owning the relevant protection systems) provided detailed information regarding the protection systems on all elements connected to the bus. The presence of single points of failure was then assessed at the component level of a protection system, which consists of protective relays, communication systems, AC current and voltage inputs, and DC control circuitry. It should be noted that in some instances stability simulations were conducted prior to any review of the actual applied Protection Systems, while in other instances, the protection system owners may have conducted a preliminary assessment of the initial list of buses prior to simulations being conducted. Protection system owners evaluated the components of a protection system against the attributes defined in Table 1.3 below, which is Table B from the Data Request.

Table 1.3: Protection System Attributes to be Evaluated
Protective Relays: The protection system includes two independent protective relays that are used to measure electrical quantities, sense an abnormal condition such as a fault, and respond to the abnormal condition.
Communication Systems: The protection system includes two independent communication channels and associated communication equipment when such communication between protective relays for communication-aided protection functions (i.e., pilot relaying systems) is needed to satisfy system performance required in NERC Reliability Standards TPL-002-0b and TPL-003-0a.
AC Current and Voltage Inputs: The protection system includes two independent AC current sources and related inputs, except that separate secondary windings of a free-standing current transformer (CT) or multiple CTs on a common bushing can be used to satisfy this requirement; and includes two independent AC voltage sources and related inputs, except that separate secondary windings of a common capacitance coupled voltage transformer (CCVT), voltage transformer (VT), or similar device can be used to satisfy this requirement.
DC Control Circuitry: The protection system includes two independent DC control circuits with no common DC control circuitry, auxiliary relays, or circuit breaker trip coils. For the purpose of this data request the DC control circuitry does not include the station DC supply or the main DC distribution panel(s), but does include all the DC circuits used by the protection system to trip a breaker, including any DC control circuit (branch) fuses or breakers at the main DC distribution panel(s).

Data was collected separately for the station DC supply. This data was collected on DC supplies to all of the 3,916 buses that meet the Table A criteria. Station DC supply data was collected to assess the incidence of two station DC supplies as well as the level of monitoring for buses with only one station DC supply. See the station DC supply attributes to be reported in Table 1.4 below, which is Table D from the Data Request.

Table 1.4: Station DC Supply Attributes to be Reported
The protection system includes two independent station DC supplies
The protection system includes one station DC supply that is centrally monitored; if the station DC supply is a battery the monitoring includes alarms for both low voltage and a battery open condition
The protection system includes one station DC supply that is centrally monitored; the station DC supply is a battery and the monitoring does not include alarms for both low voltage and a battery open condition
The protection system includes one station DC supply that is not centrally monitored

Entities submitted data in a tabular format as described in the Data Request. The output of the collected data is collated in the following eight tables (see Appendix A).

- Table A.1 – Buses Evaluated by the Transmission Planner
- Table A.2 – Attributes of Evaluated Transmission Line Protection Systems
- Table A.3 – Attributes of Evaluated Transmission Transformer Protection Systems
- Table A.4 – Attributes of Evaluated Generator Step-Up Transformer Protection Systems
- Table A.5 – Attributes of Evaluated Step-Down Transformer Protection Systems
- Table A.6 – Attributes of Evaluated Shunt device Protection Systems
- Table A.7 – Attributes of Evaluated Bus Protection Systems
- Table A.8 – Station DC Supply Attributes

The data for each table, aggregated for all responding entities across North America, is presented in Appendix A. Row 4 of Table A.1 contains the subset of buses that contain at least one Protection System where a failure to trip due to an existing single point of failure would result in one of the performance issues listed in Table 1.2. The data in Tables A.2 through A.7 are dependent on the methodology used by the reporting entity in identifying the buses in Row 4 of Table A.1. The assessment in this report is based on extensive discussion recognizing the variability of the data. The SPCS and SAMS have recognized this variability in the following discussion of the data. While in some cases this variability prevents definitive quantitative statements, the SPCS and SAMS consider the data to be sufficient to draw valid conclusions based on a qualitative but technical assessment.

Table A.1: Buses Evaluated by the Transmission Planner

The data in Table A.1 provides general insight regarding the buses evaluated by the Transmission Planners and includes the following information for each voltage range:

1. the total number of buses,
2. the number of buses that met the Table 1.1 criteria (Data Request, Table A) for further review,
3. the number of buses that were evaluated using actual clearing times
4. the number of buses for which a simulation based on actual clearing times exhibited at least one of the adverse impacts in Table 1.2 (Data Request, Table C).

Table A of the Data Request included the criteria shown in Table 1.1 to focus the analysis on those buses more likely to have a significant impact on the stability of the bulk power system. Limiting the number of buses significantly reduced the effort required of responding entities while still providing NERC a data population sufficient to draw valid conclusions. The criteria in Table 1.1 included the number of circuits connected to the bus, whether the bus directly supplies off-site power to a nuclear generating station, and whether the Transmission Planner believes for any other reason that the bus is necessary for the reliable operation of the bulk power system. For the purpose of applying the Table 1.1 criteria, the number of circuits connected includes any elements that represent a significant source of fault current (i.e., transmission lines, transmission transformers with the primary terminal and at least one secondary terminal operated at 100 kV or higher, and generator step-up transformers connecting generating resources with aggregate gross nameplate rating greater than 20 MVA). These criteria resulted in a large enough sample of data to draw valid conclusions. This conclusion is based on both the number and percentage of buses in each voltage range that met the criteria in Table 1.1. At the high-voltage (HV) levels (up to 230 kV), entities tested over 1,000 buses in each voltage range. At the extra high-voltage (EHV) levels (greater than 230 kV), entities tested over one-half of the total number of buses.

The reporting entities identified the following numbers of buses meeting the requirements of Table A in the data request:

- 1,522 buses (7 percent of all buses) operated at 100–199 kV,
- 1,310 buses (34 percent of all buses) operated at 200–299 kV,
- 768 buses (57 percent of all buses) operated at 300–399 kV,
- 262 buses (67 percent of all buses) operated at 400–599 kV, and
- 54 buses (81 percent of all buses) operated at 600 kV and above.

Table 1.5: Buses Evaluated by the Transmission Planner

Row	Description	100-199 kV	200-299 kV	300-399 kV	400-599 kV	≥600 kV
1	Total number of buses in the transmission planning area	21,817	3,848	1,350	392	67
2	Total number of buses in the transmission planning area that meet the criteria in Table A, "Initial Criteria for Buses to be Tested"	1,522	1,310	768	262	54
	Percentage of buses in the transmission planning area that meet the criteria in Table A, "Initial Criteria for Buses to be Tested"	7%	34%	57%	67%	81%

In general, the short-circuit strength at a bus is indicative of the potential risk that a prolonged fault will impact reliable operation of the bulk power system. Therefore, on a qualitative basis, the set of buses that met the criteria in Table A is more likely to include buses at which a protection system single point of failure may result in an adverse impact to reliability of the bulk power system than the buses with fewer connected circuits.

Rows 3 and 4 of Table A.1 provide information on the number of buses evaluated based on maximum expected clearing times and the number of buses at which simulation of a three-phase fault and a protection system single point of failure indicate system performance that exhibits at least one of the adverse impacts in Table 1.2 of the Data Request. The adverse impacts are indicative of a risk to reliable operation of the bulk power system and include the following:

- loss of synchronism of generating units totaling greater than 2,000 MW or more in the Eastern or Western Interconnections, or 1,000 MW or more in the ERCOT or Québec Interconnections,
- loss of synchronism between two portions of the system, and
- negatively damped oscillations.

Although various equivalent methodologies were allowed, the data in Row 4 is essentially the number of buses with both a Table C performance issue and the presence of a Protection System with a single point failure issue. This may overstate the problem somewhat, as not all SPF result in a failure to trip, and that many SPF will result in actual clearing times that are less than those resulting from a bus fault. Never the less, viewing the data in rows 3 and 4 of Table 1.6 in relation to each other demonstrates that, in general, the probability that a failure of a protection system to clear a fault will impact reliable operation exists and increases at higher voltages as shown in the table.

Table 1.6: Buses Evaluated by the Transmission Planner						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
3	Total number of buses evaluated by the Transmission Planner based on actual clearing times	716	813	356	164	44
4	Total number of buses evaluated by the Transmission Planner based on actual clearing times that resulted in system performance exhibiting any adverse impact defined in Table C, “Performance Measures”	160	316	212	101	43
	Percentage of buses evaluated by the Transmission Planner based on actual clearing times that resulted in system performance exhibiting any adverse impact defined in Table C, “Performance Measures”	22%	39%	60%	62%	98%

However, this information alone does not indicate a reliability concern. Assessment of this reliability concern is a function of both the potential consequence and the exposure to a single point of failure. Thus, it is necessary to analyze the Table A.1 data in conjunction with the protection system attributes data in Tables A.2–A.7.

Tables A.2–A.7 Data: Attributes of Evaluated Protection Systems

Data in Tables A.2–A.7 provides insight into the presence of single points of failure for various power system elements (transmission lines, transmission transformers, generator step-up transformers, step-down transformers, shunt devices, and buses). These tables provide information on the total number of protection systems evaluated, the number that contain a single point of failure, and the presence of single points of failure by components of a protection system: protective relays, communication systems, AC current and voltage inputs, and DC control circuitry (see Table 1.3). The data collected in Tables A.2-A.7 for DC control circuitry includes auxiliary relays and trip coils but excludes the station DC supply. Data for the station DC supply was collected separately in Table A.8.

The single points of failure reported in Tables A.2–A.7 are related to the buses at which the Transmission Planner identified a potential risk, based on simulation of a three-phase fault and protection system single point of failure using maximum expected clearing times. In developing the requested data, simulations performed by the Transmission Planners were based on the assumption that a component failure of a protection system associated with a single point of failure would, in all cases, result in a failure to trip. This assumption provided a conservative and uniform method for simulating faults. However, the impact of a single component failure will not always result in a protection system failure to trip, depending on the component that fails and the design of the overall protection system. This subject is discussed further for each component type in the following subsections of this report. The discussion of component types is arranged according to the perceived risk to reliability associated with a single point of failure, based on the experience of the SPCS and SAMS members. Technical analysis relative risk of various categories of failure is included in the next section of this chapter.

DC Control Circuitry

A single point of failure in DC control circuitry will result in the failure of a given protection system to trip and, depending on its design and the location of the failure, may also result in a failure to initiate breaker failure protection.

As discussed at the 2011 FERC Technical Conference on single points of failure, the single point of failure concern originated in a NERC Alert[6] based on the negative outcomes of three significant events. The root cause of these three events was the failure of a single relay (an auxiliary relay or lockout relay). Auxiliary relays and lockout relays are included in the DC control circuitry protection system attribute. These relays are generally unmonitored devices and, thus, may fail and remain undetected until they are periodically tested. Auxiliary relay failures in designs that include use of a single auxiliary relay for multiple functions will result in prolonged fault duration, particularly where a single auxiliary relay is used for both tripping and breaker failure initiation.

Protective Relays

A single point of failure of a protective relay poses a similar exposure to prolonged fault duration as that of failure of a DC control circuit; however, the risk depends on the relay type and protection system design. Many protection system designs using electromechanical relays are configured such that a failure of one relay will be backed up to some degree by other relays (i.e., an electromechanical protection system design is typically is made up of multiple relays and more than one may respond to a given fault). Similar to an auxiliary relay, an electromechanical relay may fail and the failure may remain undetected until the relay is tested. On the other hand, microprocessor relay may be monitored through an entity's supervisory control and data acquisition (SCADA) system; thus, most failure modes can be detected and addressed, in which cases the risk to the system is reduced to a relatively short period of time.

Communication Systems

A single point of failure in a communication system poses a lower level of risk. The Data Request only analyzed communication equipment in protection systems where communication-aided protection is needed to satisfy the system performance required in NERC Reliability Standards. The risk associated with a given protection system is dependent on the protection system design. Depending on the protection system design, a single point of failure may result in a failure of the communication-aided system to initiate a high-speed trip (e.g., a permissive overreaching transfer trip scheme), in which case delayed tripping will occur. In other designs, a communication system failure will not prevent high-speed tripping (e.g., a directional comparison blocking scheme).

Communication systems, regardless of vintage or design, are typically monitored and alarmed via SCADA or tested periodically.

AC Current and Voltage Inputs

A single point of failure in AC current and voltage inputs poses a lower level of risk of failure to trip. Instrument transformers are generally more robust than the other components of a protection system analyzed in the Data Request. However, cable runs, fuses, and terminations have a similar susceptibility to failure as DC control circuitry.

In most cases, a current circuit failure will result in an imbalance, which may result in a trip. In differential or ground overcurrent applications on transmission lines, buses, transformers, or shunt devices, AC current input

---

[6] Industry Advisory, Protection System Single Point of Failure, March 30, 2009. (http://www.nerc.com/fileUploads/File/Events%20Analysis/A-2009-03-30-01.pdf).

failure will typically cause a circuit to trip at a certain load or fault level. Additionally, where AC current input circuits are monitored via SCADA, loss of a current input may be identified by automated devices or dispatch personnel.

Most microprocessor relays alarm for a loss of potential via SCADA; thus, the time that failed equipment is connected to the system can be minimized. Most electromechanical relays that use voltage inputs are prone to tripping on loss of a single-phase voltage (the most common AC voltage input failure). Additionally, where AC voltage input circuits are monitored via SCADA, low voltage due to a circuit failure may be alarmed.

Overall Order 754 Data Interpretation

Below 600kV, simulated testing showed that the probability of a three-phase fault accompanied by a protection system failure could result in the adverse system impacts listed in Table 1.2. The probability of an adverse impact decreased as the voltage class was lowered. At these voltage levels, a significant percentage of protection systems included single points of failure. This data shows that the chance of an adverse system impact due to a single point of failure at buses as low as 100kV exists, and leads to the conclusion that some risk mitigating action must be taken.

Above 600kV, simulated testing showed that the probability of a three-phase fault accompanied by a protection system failure resulting in an adverse system impact was high. However, almost all protection system equipment was fully redundant at that voltage level. The data shows that the chance of an adverse system impact due to a single point of failure at 600 kV and above is low.

Chapter 2 – Alternatives

The SPCS and SAMS considered the following alternatives in order of preference for addressing reliability risks associated with single points of failure:

Standards Development Process

Modify Reliability Standard TPL-001-4 – Transmission System Planning Performance Requirements

- Modify footnote 13 to include, at a minimum, protective relays, DC control circuitry, and station DC supply
- Place additional emphasis on assessment of a three-phase fault and protection system failure
  - Keep as an extreme event, but require studies of instances of single points of failure
    - Provides assurance that areas where a three-phase fault accompanied by a single point of failure that will cause an adverse impact are identified and evaluated
  - Elevate to a planning event with its own system performance criteria
    - Probability of three-phase fault with a protection system failure is low enough that it does not warrant a planning event
  - Keep as an extreme event with no change (other than footnote 13)
    - Does not provide assurance a three-phase fault with protection system failure is studied in planning assessments
- Include a Guidelines and Technical Basis section related to the revisions pertaining to the study of protection system failures

Create a New Standard Addressing the Study of Protection System Single Points of Failure

- Remove relay failure from TPL-001-4 and create a separate TPL (transmission planning) or PRC (protection and control) standard on the study of protection system single points of failure (including the same options as the previous alternative)
  - Accomplishes same objective as modifying TPL-001-4
  - Retaining in TPL-001 is more efficient and keeps all planning tests in one standard (i.e., reason for combining TPL-001 through TPL-004)

Create a New Standard Requiring Redundant Protection Systems on BES Elements

- Create protection system redundancy PRC standard requiring redundant protection systems for all BES Elements
  - Not an efficient way to address the problem (precludes other solutions)
  - Promotes a zero-defect approach rather than a risk-based approach

Reliability Guideline

- Provides insight into modeling protection system failures in planning assessments
- Provides insight into evaluation of risk of a single point of failure

- Does not provide assurance a three-phase fault with protection system failure is studied in all planning assessments

NERC Alert

- Raises awareness based on findings from the Data Request
- Does not provide assurance a three-phase fault with protection system failure is studied in all planning assessments

Chapter 3 – Conclusion

Analysis of the data demonstrates the existence of a reliability risk associated with single points of failure in protection systems that warrants further action. The analysis shows that the risk from single point of failure is not an endemic problem and instances of single point of failure exposure are lower on higher voltage systems. However, the risk is sufficient to warrant further action. Risk-based assessment should be used to identify protection systems of concern (i.e., locations on the BES where there is a susceptibility to cascading if a protection system single point of failure exists). Not all failures adversely affect reliable operation of the bulk power system. The reliability risk varies based on which component of a protection system fails.

Additional emphasis in planning studies should be placed on assessment of three-phase faults involving protection system single points of failure. This concern (the study of protection system single points of failure) is appropriately addressed as an extreme event in TPL-001-4 Part 4.5. From TPL-001-4, Part 4.5: If the analysis concludes there is cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

Any modifications to a NERC standard must be made through the NERC Standards Process under the NERC rules of Procedure. Regarding single points of failure in protection systems, the SPCS and SAMS make the following recommendations to a Standards Drafting Team that may be formed for modifying TPL-001-4.:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace "relay" with "component of a Protection System," and
  - Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase "or a relay failure[13]" from items a, b, c, and d to create distinct events only for stuck breakers.
  - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure[13]" with "a component failure of a Protection System[13]."
- Replace footnote 13 in TPL-001-4 with, "The components from the definition of "Protection System" for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."[7]
- Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

Appendix A – Order No. 754 Data

Table A.1: Buses Evaluated by the Transmission Planner						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of buses in the transmission planning area	21,817	3,848	1,350	392	67
2	Total number of buses in the transmission planning area that meet the criteria in Table A, "Initial Criteria for Buses to be Tested"	1,522	1,310	768	262	54
3	Total number of buses evaluated by the Transmission Planner based on actual clearing times	716	813	356	164	44
4	Total number of buses evaluated by the Transmission Planner based on actual clearing times that resulted in system performance exhibiting any adverse impact defined in Table C, "Performance Measures"	160	316	212	101	43

Table A.2: Attributes of Evaluated Transmission Line Protection Systems						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of transmission line terminals at which protection system attributes were evaluated by the Generator Owners, Transmission Owners, and Distribution Providers	2,227	1,799	1,625	402	182
2	Number of transmission line terminals at which the protection system does not meet all of the specified protection system attributes for redundancy in Table B	1,190	996	227	270	12
3	Number of transmission line terminals at which the protection systems does not meet the specified protection system attributes for the protective relays	229	25	4	0	0
4	Number of transmission line terminals at which the protection systems does not meet the specified protection system attributes for the communication systems	364	301	42	7	0
5	Number of transmission line terminals at which the protection systems does not meet the specified protection system attributes for the AC current and voltage inputs	960	581	182	99	12
6	Number of transmission line terminals at which the protection system does not meet the specified protection system attributes for the DC control circuitry	785	642	42	205	0

Table A.3: Attributes of Evaluated Transmission Transformer Protection Systems						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of Transmission Transformers for which protection system attributes were evaluated by the Generator Owners, Transmission Owners, and Distribution Providers	382	519	559	129	87
2	Number of transmission transformers for which the protection system does not meet all of the specified protection system attributes for redundancy in Table B	186	297	188	63	3
3	Number of transmission transformers for which the protection system does not meet the specified protection system attributes for the protective relays	66	92	121	12	3
4	Number of transmission transformers for which the protection system does not meet the specified protection system attributes for the AC current and voltage inputs	81	135	33	3	3
5	Number of transmission transformers for which the protection system does not meet the specified protection system attributes for the DC control circuitry	143	260	131	51	0

Table A.4: Attributes of Evaluated Generator Step-Up Transformer Protection Systems						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of generator step-up transformers for which protection system attributes were evaluated by the Generator Owners, Transmission Owners, and Distribution Providers	251	315	167	52	29
2	Number of generator step-up transformers for which the protection system does not meet all of the specified protection system attributes for redundancy in Table B	127	151	27	16	0
3	Number of generator step-up transformers for which the protection system does not meet the specified protection system attributes for the protective relays	68	66	12	4	0
4	Number of generator step-up transformers for which the protection system does not meet the specified protection system attributes for the AC current and voltage inputs	79	60	15	1	0
5	Number of generator step-up transformers for which the protection system does not meet the specified protection system attributes for the DC control circuitry	107	118	13	13	0

Table A.5: Attributes of Evaluated Step-Down Transformer Protection Systems						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of step-down transformers for which protection system attributes were evaluated by the Generator Owners, Transmission Owners, and Distribution Providers	345	182	32	11	0
2	Number of step-down transformers for which the protection system does not meet all of the specified protection system attributed s for redundancy in Table B	211	101	16	5	0
3	Number of step-down transformers for which the protection system does not meet the specified protection system attributes for the protective relays	62	25	6	4	0
4	Number of step-down transformers for which the protection system does not meet the specified protection system attributes for the AC current and voltage inputs	134	53	2	0	0
5	Number of step-down transformers for which the protection system does not meet the specified protection system attributes for the DC control circuitry	165	88	14	1	0

Table A.6: Attributes of Evaluated Shunt Device Protection Systems						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of shunt devices for which protection system attributes were evaluated by the Generator Owners, Transmission Owners, and Distribution Providers	205	151	142	66	114
2	Number of shunt devices for which the protection system does not meet all of the specified protection system attributes for redundancy in Table B	90	83	38	48	0
3	Number of shunt devices for which the protection system does not meet the specified protection system attributes for the protective relays	65	19	5	8	0
4	Number of shunt devices for which the protection system does not meet the specified protection system attributes for the AC current and voltage inputs	71	44	12	3	0
5	Number of shunt devices for which the protection system does not meet the specified protection system attributes for the DC control circuitry	86	64	29	43	0

Table A.7: Attributes of Evaluated Bus Protection Systems						
Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Total number of buses for which protection system attributes were evaluated by the Generator Owners, Transmission Owners, and Distribution Providers	642	565	516	126	45

Row	**Description**	**100-199 kV**	**200-299 kV**	**300-399 kV**	**400-599 kV**	**≥600 kV**
1	Number of buses for which the station DC supply includes two independent DC supplies	548	528	590	154	54
2	Number of buses for which the station DC supply includes one DC supply that is centrally monitored, and if the station DC supply is a battery, includes alarms for both low voltage and a battery open condition	234	179	37	13	0
3	Number of buses for which the station DC supply includes one DC supply that is centrally monitored, the station DC supply is a battery, and the monitoring does not include alarms for both low voltage and a battery open condition	657	489	95	35	0
4	Number of buses for which the station DC supply includes one DC supply that is not centrally monitored	51	33	3	2	0

Note: The data in Table A.8 was collected on DC supplies for all of the 3,916 busses meeting the requirements of Table A in the data request. These are the buses in Row 2 of Table A.1.

Project 2015-10 Single Points of Failure TPL-001

Cost Effectiveness

Known Outages FERC Order No. 786

FERC Order No. 786 Paragraph 40 directs a change to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments. See paragraphs 33-45 for the discussion on planned maintenance outages.

Overview of Commission Determination (Paragraphs 40-45)

The commission stated in Order No. 786 Paragraph 41:

- For the reasons discussed below, the Commission finds that planned maintenance outages of less than six months in duration may result in relevant impacts during one or both of the seasonal off-peak periods.
- Prudent transmission planning should consider maintenance outages at those load levels when planned outages are performed to allow for a single element to be taken out of service for maintenance without compromising the ability of the system to meet demand without loss of load.
- We agree with commenters such as MISO and ATCLLC that certain elements may be so critical that, when taken out of service for system maintenance or to facilitate a new capital project, a subsequent unplanned outage initiated by a single-event could result in the loss of non-consequential load or may have a detrimental impact to the bulk electric system reliability.
- A properly planned transmission system should ensure the known, planned removal of facilities (i.e., generation, transmission or protection system facilities) for maintenance purposes without the loss of non-consequential load or detrimental impacts to system reliability such as cascading, voltage instability or uncontrolled islanding.

The Commission Disagreed with the following:

- Order No. 786 Paragraph 44: The existing TPL-001-4 for Category P3 covers generator maintenance outages, Category P6 covers transmission maintenance outages.
- Order No. 786 Paragraph 45: Planned outages of less than one year in duration should be addressed operationally by determining new operating limits and taking other actions to mitigate the planned outage.
- Order No. 786 Paragraph 45: Planned outages of less than six months is unnecessary since…10 year time frame.

Options Considered By Standard Drafting Team to Satisfy FERC Order

The following options considered by the NERC Standard Drafting Team for Requirement R1 Part 1.1.2 include (refer to SAMS recommendations):

Current Option (Draft 3):

1.1. System models shall represent:

1.1.1. Existing Facilities.

1.1.2. Known -outage(s) of generation or Transmission Facility(ies) scheduled in ~~as selected in consultation with the Reliability Coordinator for~~ the Near-Term Transmission Planning Horizon selected for analyses pursuant to Requirement R2, Parts 2.1.3 and 2.4.3 only. Known outage(s) shall be selected according to an established procedure or technical rationale that, at a minimum:

1.1.2.1. ~~for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3~~Includes known outage(s) that are expected to result in Non-Consequential Load Loss for P1 events in Table 1 when concurrent with the selected known outage(s); and

1.1.2.2. Does not exclude known outage(s) solely based upon the outage duration.

~~**1.1.2.**~~**1.1.3.** New planned Facilities and changes to existing Facilities.

~~**1.1.3.**~~**1.1.4.** Real and reactive Load forecasts.

~~**1.1.4.**~~**1.1.5.** Known commitments for Firm Transmission Service and Interchange.

~~**1.1.5.**~~**1.1.6.** Resources (supply or demand side) required for Load.

Option considered for Draft 3:

Requirement R1, Part 1.1.2 Known outages(s) of generation or Transmission Facility(ies) with duration of at least ~~six~~ four months and any other significant planned outages of generation or Transmission Facility(ies) with a duration of less than four months that are expected to produce more severe System impacts on its portion of the BES. ~~These~~ This outage coordination~~s~~ ~~are~~ is required to be performed for the season/load-levels that outages are normally planned at and shall be performed only in the Near-Term Transmission Planning Horizon.

Previous Option (Draft 2)

1.1.2 Known outage(s) of generation or Transmission Facility(ies) ~~with a duration of at least six months.~~as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

Standard Drafting Team Proposal for Requirement R1 Part 1.1.2

The SDT did not feel like a time duration alone would capture "significant outages". Additionally, the language allows PC's to develop a process for selecting "significant outages" to be studied in the Near-Term Transmission Planning Horizon.

Single Point of Failure of the Protection System

Based on Order No. 754 directive of September 15, 2011; NERC informational filing dated March 15, 2012; Section 1600 data request; and the 2nd NERC informational filing dated October 30, 2015, the SPCS/SAMS report to address the concern of Single Point Of Failure of a protection system:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace "relay" with "component of a Protection System," and
  - Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase "or a relay failure13" from items a, b, c, and d to create distinct events only for stuck breakers.
  - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure13" with "a component failure of a Protection System13."
- Replace footnote 13 in TPL-001-4 with, "The components from the definition of "Protection System" for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."[1]
- Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults with the described component failures of a Protection System13 that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

Revision By Standard Drafting Team to Satisfy FERC Order

Since some of the recommendations from the SPCS and SAMS report were so specific, there were no other options considered for the following:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace "relay" with "component of a Protection System," and

- Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.

- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase "or a relay failure" from items a, b, c, and d to create distinct events only for stuck breakers.
  - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure" with "a component failure of a Protection System."

Different options were considered for footnote 13 language.

Current Option Footnote 13 (Draft 3)

1. For purposes of this standard, non-redundant components of a Protection System to consider are as follows:
   - A single protective relay which responds to electrical quantities, without an alternative (which may or may not respond to electrical quantities) that provides comparable Normal Clearing times~~, e.g. sudden pressure relaying~~;
   - A single communications system, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported at a Control Center;
   - A single station dc supply associated with protective functions required for Normal Clearing, and that single station dc supply is not monitored or not reported at a Control Center for both low voltage and open circuit;
   - A single control circuitry (including auxiliary relays and lockout relays) associated with protective functions through and including the trip coil(s) of the circuit breakers or other interrupting devices required for Normal Clearing.

Previous Option Footnote 13 (Draft 2)

The previous option was to have footnote 13 list four of the five components of a protection system but limit *"communications systems"* to only those that are not monitored or alarmed. The following is language for Footnote 13[1]:

13. For the purposes of P5 of this standard, components of a Protection System include the following:

    a. A single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying;

    b. A single communications system, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported;

[1] Failure of voltage and current sensing device would result in a breaker operation without a fault which was considered not a reliability risk to the BES.

c. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit;

~~a.~~d. A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.

Standard Drafting Team Proposal for Table 1 Footnote 13:

The Standard Drafting Team added clarifications to the previous draft option which expands Protection System components to be considered to determine the impact to the BES if that component failed when a fault occurs.

Extreme Events and P8 Category:

The SPCS and SAMS report for Order No. 754 recommended that three phase faults involving single points of failure of a protection system be addressed. Additionally, the standard drafting team recognized that the Order No. 754 data requirement collected data for a three-phase fault and not a single-line-ground fault. The Order No. 754, Section 1600 data collection and report indicated a risk to the BES for three phase faults followed by single points of failure of a protection system. Therefore, the SDT decided to make Category P8 planning event if a three-phase fault following by a single points of failure resulted in Cascading or instability.

Revision By Standard Drafting Team to Satisfy FERC Order

Current Option (Draft 3):

~~4.2.~~ Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event (s) shall be conducted.

4.2.1~~. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.~~

~~4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:~~

~~4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementationList System deficiencies, the associated actions, and an associated timetable for implementation needed to prevent the System from Cascading.~~

~~4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.~~

Previous Option (Draft 2):

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.2.1. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation~~List System deficiencies, the associated actions, and an associated timetable for implementation needed to prevent the System from Cascading~~.

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

Standard Drafting Team Proposal

The standard drafting team feels that there is a reliability risk to the BES if Cascading or instability results in a three-phase fault followed by single point of failure of a protection system. There was confusion in the industry with the language that was similar to a CAP but not exactly a CAP. Therefore, the standard drafting team decided to create a P8 planning event which required a CAP if Cascading or instability occurs.

Answer Comment:

NPCC suggests that while the TPL-001-4 standard is being revised to address single component failure, the SAR is revised to also address a point of confusing regarding testing for line end open conditions which may result in a RFI if not addressed here. Specifically TPL-001-4, footnote 7 states “Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point”

1) Does this mean opening one end of a line section with a breaker operation?

2) For line section connected to a station with a breaker and a half or ring bus design, only one breaker would be opened?

3) Using a Disconnect Switch is or is not applicable for this event?

Selected Answer: No

Answer Comment:

MH believes the proposed SAR did not completely capture the recommendations proposed in the background NERC document posted in the project page. The SAR recommends to simply replace the “relay” with “components of protection system” and to replace foot note 13 with the definition of “Protection System” under Categary-5 in Table-1 of TPl-001-4. The category P5 in Table-1 of TPL-001-4 recommends simulating a single-line-to-ground (SLG) fault, but the proposed SAR is recommending to modify the section 4.5 of the TPL standard to simulate a three-phase fault (simulation of a three-phase fault is proposed by NERC SPCS and SAMS in their background document)

Based on the background document from SPCS and SAMS, it appears that a breaker with a single trip coil is OK from a redundancy point of view if it is the only single point of failure and can be simulated as a breaker failure event. A risk based assessment should be used to identify locations of concern rather than making full protection redundancy a bright line requirement (such as all stations 100 kV and above). The background document provided a criteria for busses to be evaluated (Table 1.1) and criteria to evaluate the system performance (Table 1.2). These ideas don’t seem to be in the SAR.

MH is proposing to introduce a separate category (or to modify Category P5) in Table 1 of TPL-001-4 to simulate a three-phase fault only for the busses meeting the criteria in Table 1.1 in the NERC background document and to evaluate the system performance against the criteria given in Table 1.2.

Answer Comment:

PSEG provides input below suggesting improvements to several parts of the SAR.

1. **Section entitled "Industry Need (What is the industry problem this request is trying to solve?)"** This section is too detailed. The project's webpage should have the final Order 754 Section data request posted in addition to the presently posted September SCPS/SAMs report and should have links to both documents. It should state that the SAR is a product of both documents – the Section 1600 data request and the SCPS and SAMS report which analyzed the results of that data request and developed recommendations and conclusions. The SAR need not repeat those recommendations and conclusions in the SAR itself.

2. **Section entitled "Purpose or Goal (How does this request propose to address the problem described above?)"** The present language limits the SDT to making recommendations identified in the SPCS and SAMS report. While such recommendations may be considered by the SDT, the SAR should not prevent the SDT from making

recommendations that differ from those in the SCPS and SAMS report. With this in mind, the following purpose statement is offered for consideration:

The primary goal of this SAR is to modify NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) for the purpose of clarifying which Protection System components shall be included within the single point of failure analyses required by this Standard. The SDT shall give due weight to and consideration of the recommendations in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request."

3. Section entitled "Identify the Objectives of the proposed standards' requirements (What specific reliability deliverables are required to achieve the goal?)" This section has limitations that are similar to the prior sections. Again, the language should no limiting the SDT's work product to the modifications recommended in the SCPS and SAMS report. The following language is offered for consideration.

Provide clear, unambiguous requirements and results-based Reliability standards to address the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) that achieve the primary goal in the preceding section."

4. **Section entitled "Brief Description (Provide a paragraph that describes the scope of this standard action.)"** No comments.

5. **Section entitled "Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR. Also provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)"** We recommend one word change to the first sentence which further supports the Purpose and Goal section as modified above:

The SDTs execution of this SAR requires the SDT to [address - strike "**address"** and replace with "**consider"**] the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request."

RoLynda Shumpert - SCANA - South Carolina Electric and Gas Co. - 1,3,5,6 - SERC

Selected Answer: No

Answer Comment:

South Carolina Electric and Gas agrees with The SERC Planning Standards Subcommittee below:

"The original Order 754 work was based on a selection of a subset of transmission buses (the larger stations), rather than the entire BES. There does not appear to be anything in the SAR which limits the scope of the applicability in a similar fashion. We are concerned about the potential for inadvertently drastically increasing assessment work load if the scope is not appropriately limited. "

Selected Answer: No

Answer Comment:

Drop the “Modify TPL-001-4 (Part 4.5)” item from the SAR. The existing Part 4.5 text already includes the obligation to consider all (i.e. item number 1 and item number 2) of the stability extreme event items in Table 1. There is no need to add more text to make duplicative reference to item number 2.

Consider adding other items to the scope of the SAR to address several specific deficiencies that have been found in the TPL-001-4 standard.

- **Table 1, Header note i** – Revise note i because the present text can be interpreted to contradict the NERC Definition for Non-Consequential Load Loss. The response of voltage sensitive load and load disconnected from the System by end-user equipment are not Non-Consequential Load Loss. So by definition, response of voltage sensitive load and load disconnected from the System by end-user equipment are excluded from the steady state Non-Consequential Load Loss Allowed performance requirement. Wording like, “. . . associated with a planning event is allowed” may be clearer and not contradictory.
- **Cascading clarification** – Clarify the understanding the NERC definition of Cascading (e.g. Table 1, header note a). The subsequent loss of system elements, load, or generation is classified as Cascading when it results in widespread electric service interruption. Therefore, the loss of line circuits, transformer circuits, generators, or limited amounts of load due to cascading does not qualify as exceeding the Cascading performance requirement.
- **Load loss due to cascading** – Address the treatment of load loss due to cascading - perhaps with an additional Table 1 footnote. Load loss due to cascading does not meet the NERC definition of either Consequential Load Loss or Non-Consequential Load Loss. So, cascading load loss does not apply to the Non-Consequential Load Loss Allowed performance requirement. However, an additional performance requirement should probably be added that the sum of cascading load loss and Non-Consequential Load Loss should not exceed an entity’s IROL criteria.
- **Use of sensitivity cases in extreme event analysis** – Revise the wording in R3 and R4 (e.g. referring to Part 2.1 or Part 2.4 without limiting the obligation to planning event studies) to remove the obligation to use sensitivity cases in extreme event studies (i.e. R3.2 and R4.2). Extreme event studies using baseline cases (R2.1.1, R2.1.2, R2.2.1, R2.4.1, and R2.4.2) are essentially probing studies that consider extraordinary contingencies. Extreme event studies using sensitivity cases (R2.1.4 and R2.4.3) are essentially probing studies that consider the compounded effect of both extraordinary contingencies and extraordinary system conditions. The obligation to perform these compound effect studies results in an unreasonable expenditure of resources compared to the

information gained regarding potential consequences and adverse impacts.

- **Transfer levels used in near term planning horizon System models** – Include wording (perhaps in R2.1.4 – Expected transfers and R2.4.3 – Expected transfers) which explains that expected transfers used in the sensitivity cases must not exceed Transfer Capabilities assessment results that were determined in accordance with the effective NERC FAC-013 Reliability Standard.
- **Table 1, Footnote 1** – Revise the wording of footnote 1 of Table to add more clarity. For example, that an element is removed, not just open ended, by a Protection System operation designed to isolate the event fault. The voltage level of an unloaded winding of a three-winding transformer is excluded from the determination.

Amy Casuscelli - Xcel Energy, Inc. - 1,3,5,6 - MRO,WECC,SPP

Selected Answer: No

Answer Comment:

Due to the length of time (several years) it took the NERC SDT to develop the final draft, gain industry acceptance and receive FERC approval of the NERC TPL-001-4 standard, we believe that a more comprehensive review is essential at this time to address the ambiguities and enhance clarity in the standard. Therefore, we strongly suggest that the SAR's scope not be limited to just the single point of failure concern resulting from FERC Order No. 754, but be expanded to address all significant issues & concerns identified based on the standard's implementation experience by applicable entities in the industry.

Some of the numerous TPL-001-4 issues & concerns based on Xcel Energy's diverse planning experience in three Regions (MRO, SPP, WECC) are noted below. Additionally, we also support the issues identified by MRO NSRF, which are included as part of our comments under Q.2.

1. Requirement 1 references two standards, MOD-010 and MOD-012, that are slated to retire on July 1, 2016.
2. Requirement 2 requires independent Planning Assessments by both the Planning Coordinator/Authority (PC/PA) and Transmission Planner (TP), yet Requirement 7 states that the PC/PA in conjunction with the TP shall identify each entity's responsibility in completing what may be a single Planning Assessment. We believe that these two Requirements can be consolidated into one better defined Requirement.
3. Both sub-requirements 2.3 and 2.8 address the short circuit analysis required in the Planning Assessment. These are closely interrelated and can be consolidated into one Requirement.
4. Requirement 8 states that TPs shall distribute the Planning Assessment results to adjacent TPs and PCs. In discussion with other TPs, they are not necessarily interested in receiving Planning Assessments from other TPs, but do believe that if a reliability need arises, these should be made available upon request.

Since project 2015-10 will make substantial modifications to the TPL-001-4 standard, we respectfully ask NERC to take this opportunity to include a comprehensive review of the standard within the SAR's scope andhelp address the issues & concerns faced by many in the industry.

Leonard Kula - Independent Electricity System Operator - 2 -

Selected Answer: Yes

Answer Comment:

While we generally support the scope and direction proposed in the SAR, some of the proposed changes to TPL-001-4 described in the SAR (and in this Comment Form) are unclear. Hence, we reserve our judgment on the final scope and the specific changes that will be made to the TPL-001-4 standard. For example, the replacement of FN 13 with the proposed wording but there is no mention of the placement of the functions or types of relay that will be replaced. Further, the meaning of "evaluation of the three-phase faults the described component failures of a Protection System" in the last bulleted proposed change is unclear. Does it mean evaluation of a three phase fault combined with the component failure of a Protection System? This needs to be clarified.

Joe Tarantino - Sacramento Municipal Utility District - 1,3,4,5,6 - WECC

Selected Answer: Yes

Answer Comment:

Given the primary goal of this SAR is to appoint a SDT to address recommendations for modifying the NERC Reliability Standard TPL-001-4 it is expected that the SDT would address FERC issues for single points of failure.

However, the SAR contains specific changes from the SPCS report that were recommendations from that team. There were other alternatives identified in the report that should be vetted by a broader audience.

Andrew Pusztai - American Transmission Company, LLC - 1 -

Selected Answer: No

Answer Comment:

Under SAR Information (Industry Need) - ATC has the following recommendations for the SAR SDT to consider:

(1) Please drop the "Modify TPL-001-4 (Part 4.5)" item from the SAR. The existing Part 4.5 text already includes the obligation to consider all (i.e. item number 1 and item number 2) of the stability extreme event items in Table 1. There is no need to add more text to make duplicative reference to item number 2.

(2) **Under SAR Information (page 2) - In addition to the SCPS and SAMS recommendations, ATC recommends the SAR SDT also consider adding other items to the scope of the SAR to address several specific deficiencies that have been found in the TPL-001-4 standard.**

· **Table 1, Header note i** – Please revise note i because the present text can be interpreted to contradict the NERC Definition for Non-Consequential Load Loss. The response of voltage sensitive load and load disconnected from the System by end-user equipment are not Non-Consequential Load Loss. So by definition, response of voltage sensitive load and load disconnected from the System by end-user equipment are excluded from the steady state Non-Consequential Load Loss Allowed performance requirement. Wording like, ". . . associated with a planning event is allowed" may be clearer and not contradictory.

· **Cascading clarification** – Please clarify the understanding the NERC definition of Cascading (e.g. Table 1, header note a). The subsequent loss of system elements, load, or generation is classified as Cascading when it results in widespread electric service interruption. Therefore, the loss of line circuits, transformer circuits, generators, or limited amounts of load due to cascading does not qualify as exceeding the Cascading performance requirement.

· **Load loss due to cascading** – Please address the treatment of load loss due to cascading - perhaps with an additional Table 1 footnote. Load loss due to cascading does not meet the NERC definition of either Consequential Load Loss or Non-Consequential Load Loss. So, cascading load loss does not apply to the Non-Consequential Load Loss Allowed performance requirement. However, an additional performance requirement should probably be added that the sum of cascading load loss and Non-Consequential Load Loss should not exceed an entity's IROL criteria.

· **Use of sensitivity cases in extreme event analysis** – Please revise the wording in R3 and R4 (e.g. referring to Part 2.1 or Part 2.4 without limiting the obligation to planning event studies) to remove the obligation to use sensitivity cases in extreme event studies (i.e. R3.2 and R4.2). Extreme event studies using baseline cases (R2.1.1, R2.1.2, R2.2.1, R2.4.1, and R2.4.2) are essentially probing studies that consider extraordinary contingencies. Extreme event studies using sensitivity cases (R2.1.4 and R2.4.3) are essentially probing studies that consider the compounded effect of both extraordinary contingencies and extraordinary system conditions. The obligation to perform these compound effect studies results in an unreasonable expenditure of resources compared to the information gained regarding potential consequences and adverse impacts.

· **Transfer levels used in near term planning horizon System models** – Please include wording (perhaps in R2.1.4 – Expected transfers and R2.4.3 – Expected transfers) which explains that expected transfers used in the sensitivity cases must not exceed Transfer Capabilities assessment results that were determined in accordance with the effective NERC FAC-013 Reliability Standard.

· **Table 1, Footnote 1** – Please revise the wording of footnote 1 of Table to add more clarity. For example, that an element is removed, not just open ended, by a Protection System operation designed to isolate the event fault. The voltage level of an unloaded winding of a three-winding transformer is excluded from the determination.

William Temple - PJM Interconnection, L.L.C. - 2 - SERC,RFC

Selected Answer: Yes

Answer Comment:

While PJM generally supports the scope and direction in the proposed SAR, some of the proposed changes to TPL-001-4 presented in the SAR (and in the Comment Form) are unclear. Therefore, we reserve our judgment on the final scope and the specific changes that will be made to the TPL-001-4 standard. For example, the replacement of Footnote 13 with the proposed wording seems fine, but there is no mention of the placement of the functions or types of relay that will be replaced. Further, the meaning of "evaluation of the three-phase faults the described component failures of a Protection System" in the last bulleted proposed change is unclear. Does it mean evaluation of a three phase fault combined with the component failure of a Protection System? This needs to be clarified.

Entity	**Region(s)**
PPL NERC Registered Affiliates	SERC,RFC

Selected Answer: No

Answer Comment:

These comments are submitted on behalf of the following PPL NERC Registered Affiliates ("PPL"): Louisville Gas and Electric Company, Kentucky Utilities Company and PPL Electric Utilities Corporation. The PPL NERC Registered Affiliates are registered in two regions (RF and SERC) for one or more of the following NERC functions: BA, DP, GO, GOP, IA, LSE, PA, PSE, RP, TO, TOP, TP, and TSP.

PPL NERC Registered Affiliates believe that this SAR usurps the SDT's role by providing specific language for inclusion in a first draft of TPL-001-5. This is atypical for a SAR form and necessitates comments on a standard even before the standard's first draft. Additionally, the SAR does not include a reliability justification for the revision in the "Detailed Description" section and instead incorporates the SPCS/SAMS report (Order No. 754…) in its entirety. PPL NERC Registered Affiliates believe that, at a minimum, a SAR should include a summary of the justification for any revisions with the SAR form itself.

PPL NERC Registered Affiliates suggest that the SDT consider adding the following language to the standard if the proposed change is added to TPL-001 for Project 2015-10 Single Points of Failure, November 2015.

“For 36 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 36 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, a correction action plan will not be required for a P5 event where an induction motor load stability model results in a transient stability criteria violation.“

The existing standard addresses similar statements:

Requirement 2.7.3: “If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner Standard TPL-001-4 — Transmission System Planning Performance Requirements 5 or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.”

Page 1 third paragraph in section 5. “For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-4, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) That would not otherwise be permitted by the requirements of TPL-001-4:

· P5 (above 300 kV)”

While this language allows some time to build projects, dropping load as written in the above language will not alleviate a transient voltage stability violation as a result of P5 event when combined with the behavior of induction motor loads under requirement 2.4.1. In most cases, the only corrective action plan available is building a redundant protection system which requires appropriate lead times.

Answer Comment:

Yes, we agree with scope and objective of this project. Additionally, we support the fact that the drafting team will be using the recommendations provided in the SPCS and SAMS report to develop a solid foundation for this project. Also, it's pertinent to consider the issues addressing Paragraph 81 as well as retirement in the Standards Development Process. As the project develops, we understand that the SDT scope may change but, we would suggest to the drafting team to work closely with the industry and use their comments and feedback as a corner stone to developing an effective and reliable standard.

Justin Mosiman - Bonneville Power Administration - 1,3,5,6 - WECC

Selected Answer: No

Answer Comment:

Bonneville Power Administration does not agree with the proposal because the proposal does not add significant value. Relay failure represents any protection system failure and should be modeled if not redundant. Bonneville Power Administration proposes to make efforts toward removing R1.1.2 (including known outages with a duration of six months) which would be more appropriate in the operations time frame than in a planning standard. Similarly, removing R2.1.1 (system peak load for either year one or year two….) would be a
more appropriate proposal since it also is more appropriate in the operations time frame rather than a planning standard.

Answer Comment:

(1) We generally agree with the scope and intent of this project, as recommended by the SPCS and SAMS. However, the SAR should clarify the meaning of “protective relays that respond to electrical quantities.” We believe this could include other relays outside the scope of the existing standard, such as sync-check relays. The list of relays that are in scope for this standard should remain at those that clear three-phase faults or other events of operational concerns.

(2) We have similar concerns that the applicability of this standard is inclusive of all BES Elements, not the sub-set identified and analyzed as part of the Section 1600 Data Request. The findings identify that buses under 300 kV are less likely to result in an adverse impact to reliability of the Bulk Power System based from a Protection System single point of failure. Proposing to collect data for all BES Elements poses an unnecessary administrative burden on registered entities and their models, especially considering that the findings do not support additional analysis under 300 kV. Moreover, analysis results identifying issues which adversely impact the reliability of the Bulk Power System could be masked by insignificant concerns.

(3) We recommend developing a methodology for the applicability of this standard that is similar to the criteria used in the Data Request, mainly to those buses more likely to have a significant stability impact on the Bulk Power System.

Answer Comment:

1. In the Order 754 data request, only a select set of busses meeting certain criteria were to be tested. However, the recomended language in the SAR would require entities to provide additional information relating to single points of failure for all BES busses. AECI would request that the additional information required by footnote 13 be only applicable to a select set of BES busses, and that this brightline be determined by the SDT.
2. AECI is not in disagreement with the final recommendation made by the SPCS and SAMS, however we would suggest that the drafting team be able to discuss which course of action would be best. This would allow for wider industry involvement in the decision on how the study of single points of failure should be addressed.

Rachel Coyne - Texas Reliability Entity, Inc. - 10 -

Selected Answer:

Answer Comment:

Texas RE noticed the proposed language for Footnote 13 in TPL-001-4, does not match the NERC Glossary term of Protection System.

The language proposed in the SAR for “protective relays” and “DC control circuitry” largely tracks the definition of “Protection System” set forth in the NERC Glossary of Terms. The sole substantive distinction appears to be limiting the general category of “control circuitry” explicitly to “DC control circuitry” consistent with recommendation in the Order No. 754 Report.

In contrast, the SAR (and the Order No. 754 Report) places additional, qualifying language on the definition of "station DC supply" that is not contained in the definition of Protection System in the NERC Glossary of Terms. Specifically, the "Protection System" definition in the NERC Glossary of Terms includes: "Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery based dc supply)." The SAR (and the recommended language in Order No. 754 Report) qualifies this language by describing "station DC supply" as "single-station DC supply that is not monitored (i.e., not reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated)."

Texas RE recommends that the SDT use of the existing definition of station DC Supply in the NERC Glossary of Terms. Using consistent language in both Standards would help entities classify their dc supply components in a uniform manner across their compliance program.

Is the intent to create a new definition of station DC supply? If so, Texas RE recommends the SDT request comments from stakeholders regarding a new definition of station DC supply so the rationale for such change can be fully developed.

Amy Casuscelli - Xcel Energy, Inc. - 1,3,5,6 - MRO,WECC,SPP

Selected Answer:

Answer Comment:

Additionally, we also support the issues identified by MRO NSRF as outlined below:

Consider adding other items to the scope of the SAR to address several specific deficiencies that have been found in the TPL-001-4 standard.
• Table 1, Header note i – Revise note i because the present text can be interpreted to contradict the NERC Definition for Non-Consequential Load Loss. The response of voltage sensitive load and load disconnected from the System by end-user equipment are not Non-Consequential Load Loss. So by definition, response of voltage sensitive load and load disconnected from the System by end-user equipment are excluded from the steady state Non-Consequential Load Loss Allowed performance requirement. Wording like, ". . . associated with a planning event is allowed" may be clearer and not contradictory.
• Cascading clarification – Clarify the understanding the NERC definition of Cascading (e.g. Table 1, header note a). The subsequent loss of system elements, load, or generation is classified as Cascading when it results in widespread electric service interruption. Therefore, the loss of line circuits, transformer circuits, generators, or limited amounts of load due to cascading does not qualify as exceeding the Cascading performance requirement.
• Load loss due to cascading – Address the treatment of load loss due to cascading - perhaps with an additional Table 1 footnote. Load loss due to cascading does not meet the NERC definition of either Consequential Load Loss or Non-Consequential Load Loss. So, cascading load loss does not apply to the Non-Consequential Load Loss Allowed performance requirement. However, an additional performance requirement should probably be added that the sum of cascading load loss and Non-Consequential Load Loss should not exceed an entity's IROL criteria.
• Use of sensitivity cases in extreme event analysis – Revise the wording in R3 and R4 (e.g. referring to Part 2.1 or Part 2.4 without limiting the obligation to planning event studies) to remove the obligation to use sensitivity cases in extreme event studies (i.e. R3.2 and R4.2). Extreme event studies using baseline cases (R2.1.1, R2.1.2, R2.2.1, R2.4.1, and R2.4.2) are essentially probing studies that consider extraordinary contingencies. Extreme event studies using sensitivity cases (R2.1.4 and R2.4.3) are essentially probing studies that consider the compounded effect of both extraordinary contingencies and extraordinary system conditions. The obligation to perform these compound effect studies results in an unreasonable expenditure of resources compared to the information gained regarding potential consequences and adverse impacts.
• Transfer levels used in near term planning horizon System models – Include wording (perhaps in R2.1.4 – Expected transfers and R2.4.3 – Expected

transfers) which explains that expected transfers used in the sensitivity cases must not exceed Transfer Capabilities assessment results that were determined in accordance with the effective NERC FAC-013 Reliability Standard.
• Table 1, Footnote 1 – Revise the wording of footnote 1 of Table to add more clarity. For example, that an element is removed, not just open ended, by a Protection System operation designed to isolate the event fault. The voltage level of an unloaded winding of a three-winding transformer is excluded from the determination.

Answer Comment:

We have a concern in reference to the recommendations suggested in the SAR on page 2….bullet number 3. We would ask the drafting team to provide clarity on what is being suggested by this particular recommendation. In our discussion, we interpreted that the recommendation is suggesting that entities will have to obtain substantially more data than what is already required. This could cause issues in getting the study(s) completed in a proper time frame. However if that is the case, we would suggest to the drafting team to use some form of criteria limiting the study of component failures to only High Priority Facilities (for example 200kV

	and above and sub-200kV IROL facilities as in FAC-003) instead of all of the BES Elements in order to reduce the magnitude of study and data collection.

When a standard is being revised, all open issues related to that standard should be resolved. In the interest of efficiency we recommend that the two directives from FERC Order 786 be added to the scope of this SAR. For reference please see the Reliability Standards Development Plan 2016 Projects 2015-10: "From FERC Order 786:

1. Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six-month threshold could exclude planned maintenance outages of significant facilities from future planning assessments.
2. 2. Paragraph 89 directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4."

The SAR should address all directives and all changes needed in the standard.

Additional points needing clarifications which should be added to the scope of the SAR and provide needed corrections to TPL-004-1 include:

1. The SAR requires studying three phase faults with protection system failure. It is not clear how the protection systems deficiencies will be corrected, when identified, since there is no obligation to the meet performance criteria for extreme events.

2. The revised standard should formalize the process described in the Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request that was used to identify the protection systems that do not

meet the redundancy criteria. The protection systems owners will need to have obligations since they are responsible for both identifying and correcting the design deficiencies.

3. There are situations when non BES elements are connected to BES buses (e.g. radial circuits supplying loads). The SAR needs to clarify which protection systems are subject to the standard since an un-cleared close in fault on a non BES element connected to a BES bus has the same reliability consequence as an un-cleared close in fault on a BES element. Do the protection systems installed on non BES elements but connected to BES buses need to meet redundancy criteria?

4. Since the TPL-001-4 standard is going to be revised we believe there is a good opportunity to clarify the following discrepancy:

In Table 1 of the standard, the use of non-consequential load loss is allowed under Footnote 12 conditions for P1, P2, and P3 planning events for the elements operated at EHV level. However, planning events P4 and P5 do not allow the use of non-consequential load loss at EHV level.

Selected Answer:

Answer Comment:

(1) We agree with the directions given in the SAR to consider retiring requirements under Paragraph 81 criteria. However, we do have concerns that the SAR does not specify requirements within this standard, such as Requirement R4, parts 4.2 and 4.5, which would qualify for P81 criteria or further consolidation. Moreover, Requirement R1 references reliability standards MOD-010 and MOD-012 which are projected to be retired in 2016. We recommend the SAR be expanded to incorporate requirement consolidations and retirements, both current and projected.

(2) We thank you for this opportunity to provide these comments.

NERC
NORTH AMERICAN ELECTRIC
RELIABILITY CORPORATION

Standards Authorization Request Form

When completed, email this form to:
sarcomm@nerc.net

NERC welcomes suggestions for improving the reliability of the Bulk-Power System through improved Reliability Standards. Please use this form to submit your proposal for a new NERC Reliability Standard or a revision to an existing standard.

Request to propose a new or a revision to a Reliability Standard			
Proposed Standard:	Project 2015-10 Single Points of Failure TPL-001 SPCS and SAMS recommendations in response to FERC Order No. 754 (TPL-001-4)		
Date Submitted:	October 05, 2015		
SAR Requester Information			
Name:	Philip B. Winston, PE and John M Simonelli		
Organization:	Southern Company and ISO New England, Inc., respectively.		
Telephone:	404-608-5989--primary	E-mail:	pbwinsto@southernco.com--primary
SAR Type (Check as many as applicable)			
☐ New Standard		☐ Withdrawal of existing Standard	
☒ Revision to existing Standards		☐ Urgent Action	

SAR Information
Industry Need (What is the industry problem this request is trying to solve?):
Modifications have been identified to Reliability Standard TPL-001-4 based on the following: Item 1: The System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) conducted a comprehensive assessment of the study of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section

SAR Information

1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.
 	
As such, regarding single points of failure in protection systems, the SPCS and the SAMS make the following recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process identified in the NERC Rules of Procedure:
 	
• For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  ▪ Replace "relay" with "component of a Protection System," and
  ▪ Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
• For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  ▪ Remove the phrase "or a relay failure[13]" from items a, b, c, and d to create distinct events only for stuck breakers.
  ▪ Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure[13]" with "a component failure of a Protection System[13]."
• Replace footnote 13 in TPL-001-4 with, "The components from the definition of "Protection System" for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."[1]
• Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults with the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

[1] See Order 754 (NERC website) Requests for Clarifications and Responses (http://www.nerc.com/pa/Stand/Order%20754%20DL/Order_754-Requests_for_Clarification_and_Responses_July2013.pdf).

SAR Information

Item 2: In addition, on October 17, 2013 the Commission issued Order No. 786, which included two directives related to TPL-001-4. The two directives are as follows:

- Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six-month threshold could exclude planned maintenance outages of significant facilities from future planning assessments
- Paragraph 89 directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4."

Item 3: Further, references to MOD-010 and MOD 012 in Requirement R1 would need to be replaced with MOD-032 due to July 2016 retirement of those standards.

Purpose or Goal (How does this request propose to address the problem described above?):

The ~~primary~~ goal of this SAR is to:

1. Consider the ~~appoint a Standard Drafting Team (SDT) to address~~ recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) as identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request";
2. Address the two FERC directives from Order No. 786; and
3. Update the references to the MOD Reliability Standards in TPL-001.

~~.~~"

Identify the Objectives of the proposed standards' requirements (What specific reliability deliverables are required to achieve the goal?):

Provide clear, unambiguous requirements and Results-based Reliability Standards that will: (1) reflect condiseration of~~standards to address~~ the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request;" (ii) address the two FERC directives from Order No. 786 citd above; and (iii) and update the references to the MOD Reliability Standards cited in TPL-001. ~~.~~"

Brief Description (Provide a paragraph that describes the scope of this standard action.)

The SDT shall consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request", address the two FERC directives, update the references to the MOD Standards,~~"~~ and revise standards, requirements, attachments, Violation Risk Factors, Violation Severity Levels, and

SAR Information
implementation plans as appropriate. The SDT shall consider retirements to requirements under Paragraph 81 criteria. In addition, the SDT shall work with compliance on an accompanying RSAW to address each of the standard's requirements and measures.
Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR. Also provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)
The SDTs execution of this SAR requires the SDT to consider~~address~~ the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request." This ~~The SDTs execution of this SAR would, in addition, consider retirements to requirements under Paragraph 81 criteria. The SPCS and SAMS~~ report ~~titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request"~~ is incorporated ~~in~~ its entirety into this SAR~~,~~ so as not to unnecessarily repeat or paraphrase the substance of the report. In addition, the SDTs execution of this SAR would consider retirements to requirements under Paragraph 81 criteria.

Reliability Functions		
The Standard will Apply to the Following Functions (Check each one that applies.)		
☐	Regional Reliability Organization	Conducts the regional activities related to planning and operations, and coordinates activities of Responsible Entities to secure the reliability of the Bulk Electric System within the region and adjacent regions.
☐	Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐	Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐	Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒	Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐	Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒	Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐	Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☐	Transmission Owner	Owns and maintains transmission facilities.

Reliability Functions		
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles	
Applicable Reliability Principles (Check all that apply).	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Reliability and Market Interface Principles	
Does the proposed Standard comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

Unofficial Comment Form

Project 2015-10 Single Points of Failure
TPL-001

Do not use this form for submitting comments. Use the electronic form to submit comments on the **Project 2015-10 Single Points of Failure Standards Authorization Request (SAR)**. The electronic form must be submitted by **8 p.m. Eastern, Friday, June 24, 2016.**

Documents and information about this project are available on the Project 2015-10 Single Points of Failure. If you have questions, contact Jordan Mallory via email or by telephone at 404-446-9733.

Background Information

The Standards Authorization Request Drafting Team (SAR DT) for Project 2015-10 Single Points of Failure (TPL-001) made changes to the first posting of the SAR based on comments received from industry. The changes include:

1) Replacing the word "address" with "consider" regarding the recommendations of the SCPS and SAMS report titled Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request.
2) Addressing the two (2) outstanding FERC directives from FERC Order No. 786:
   a. Reliability Standard TPL-001-4 requires an entity to consider planned maintenance outages greater than six months in duration in its studies. Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six-month threshold could exclude planned maintenance outages of significant facilities from future planning assessments.
   b. The spare equipment strategy for steady state analysis under Reliability Standard TPL-001-4, Requirement R2, Part 2.1.5 requires that steady state studies be performed for the P0, P1 and P2 categories identified in Table 1 with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment. Paragraph 89 directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4.
3) Updating the MOD references in Requirement R1, Measure M1 and the Violation Severity Levels sections of the TPL-001 standard to reflect the retirement of MOD-010 and MOD-012 effective July 1, 2016.

Other comments received from the November 12 through December 17, 2015 SAR comment period were reviewed. As the issues raised in these comments were determined to not present reliability risks, they were not considered in scope for this project. However, these comments may be considered during the next Enhanced Periodic Review of TPL-001.

Question

1. Do you agree with the proposed changes to the SAR? If no, please provide comments.

☐ Yes
☐ No

Comments:

Standards Announcement

Project 2015-10 Single Points of Failure
Standards Authorization Request

Informal Comment Period Open through June 24, 2016

Now Available

An informal comment period for the **Project 2015-10 Single Points of Failure** Standards Authorization Request (SAR), is open through **8 p.m. Eastern, Friday, June 24, 2016**.

Commenting

Use the electronic form to submit comments on the SAR. If you experience any difficulties in using the electronic form, contact Wendy Muller. An unofficial Word version of the comment form is posted on the project page.

If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 8 p.m. Eastern).

Next Steps

The drafting team will consider all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Standards Developer, Jordan Mallory (via email) or at (404) 446-9733.

1. Do you agree with the proposed changes to the SAR? If no, please provide comments.

Michelle Amarantos - 1,3,5,6	
Answer	No
Document Name	
Comment	

AZPS believes this creates little risk in the planning horizon. Any potential issues are best identified through next-day, real time and seasonal analysis studies (in conjunction with applicable RCs) to addresses these short duration issues, rather than through TPL-001-4. These planned maintenance outages tend to be rescheduled, as needed, in the operations horizon to account for present conditions. Including these shorter duration planned outages in the Planning Horizon would create the need for duplicative staff, duplicative equipment, additional computing time, and compliance enforcement costs related to performing additional annual planning assessments for TPL-001- 4 which are already adequately and properly covered in studies performed in the operations horizon.

As explained in detail below, Xcel Energy agrees with addressing item 1 (single points of failure) and item 3 (update the reference to MOD standards in R1) with the scope of the SAT, but disagree with item 2 (FERC directives) included in its entirety within the scope. The following comments are in reference to the items listed in the Industry Need and Purpose/Goals sections of the SAR.

Item 1: Agree with replacing "address" by "consider" in the Purpose/Goals section, but find that corresponding changes in the Industry Need section are missing. Specifically, the lead-in sentence in the Industry Need section, "*Modifications have been identified to TPL-001-4*..." implies that the SAMS/SPCS recommendations for modifying TPL-001-4 described within Item 1 are the specific changes to be implemented in TPL-001-4 . It appears that recommendations will be addressed instead of being considered.

Item 2: Agree that SAR scope may include addressing the FERC directives from Order 786. However, the scope should be limited to included "true" FERC directives, which we contend is only contained in Paragraph 40 and not in Paragraph 89. We observe the following clear distinction in the language used by FERC in Paragraph 40 versus Paragraph 89. While Paragraph 40 is certainly a directive ("directs NERC to modify Reliability Standard TPL-001-4") to address the identified (BES reliability) concern and have has the expectation that the concern would be addressed at the earliest opportunity to modify TPL-001-4, we note that Paragraph 89 does not convey a FERC directive to address the stated issue. In fact, Paragraph 89 unambiguously states "*the Commission will not direct a change and instead directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4.*" Consequently, we disagree with including Paragraph 89 within the scope of the SAR. In fact, if addressing Paragraph 89 is not deferred to the next review cycle of TPL-001-4, we see this as contradictory and inconsistent with the SAR-DT's position to defer addressing the TPL-001-4 issues and ambiguities (as identified by Xcel Energy and several other entities in comments submitted for the previous SAR posting) until the next regular review cycle of TPL-001-4. Due to the reasons cited above, we strongly recommend that addressing Paragraph 89 be excluded from the scope of this project.

Item 3: Agree with revising R1 to update reference to soon to be outdated MOD standards.

Additional editorial changes recommended below:

Industry Need Section: Another reason the lead in sentence in the Industry Need section must be revised is that addressing the Paragraph 40 directive comprehensively may require making modifications to additional standards besides TPL-001-4. For instance, modifications may be needed to the IRO-017-1, Outage Coordination, standard whose purpose and applicability has significant overlap with the reliability concern noted in Paragraph 40.

Identify the Objectives Section: Please ensure that a consistent numbering format is used for all three items. Also, please fix the spelling error typos (condiseration, citd, etc)

Detailed Description Section: Shouldn't all three items be described in this section as well? It appears that only Item 1 is described. Although it is stated that the SPCS/SAMS report "is incorporated in entirety into this SAR" we do not find it appended in the posted SAR.

Regarding Item 1: We disagree with changing the word “address” to “consider” in regards to the SPCS/SAMS recommendations. We believe the scope of the effort for item 1 should be limited to what was recommended by SPCS/SAMS. The word “consider” will allow the scope to be enlarged beyond the recommendations from the subject matter experts in the industry – SPCS/SAMS. In our opinion such changes would open the standard to many interpretations, creating significant additional study effort without clear performance-based requirements, which would also lead to future compliance issues. To the extent that the recommendations already identified and documented by SPCS/SAMS represent the best solution(s), further “consideration” by the SDT is not necessary to meet the FERC directives as this would further tie-up industry resources.

While the original FERC Order 754 work was performed with a focus on EHV facilities, there is no language in the SAR that would appear to limit the additional scope of this work in the TPL-001-4 standard to only EHV facilities, for which protection system issues would presumably have a more widespread impact to the BES. The SAR should also include the specific evaluation process and design criteria which were inlcuded in the FERC Order 754 study work. We believe the original intent of Order 754 to target EHV Facilities is a proper allocation of resources in order focus attention on Facilities with the most significant impact to the BES.

Regarding Item 2a: We are concerned with the various categories of contingencies which need to be considered already as part of system assessment work related to compliance with Reliability Standard TPL-001-4, both single and multiple element contingencies, to further give consideration to outages of less than 6 months duration would appear to be needlessly redundant. The six month time frame for including planned outages was intentionally chosen by the TPL Standard Drafting Team to be the correct time frame to make sure that outages which can cover critical peak seasons would be included in the planning analysis. Outages shorter than this are not likely to occur over critical peak seasons. Furthermore, we believe all planned outages are studied by the Operations Planning Department. They will take the necessary steps to operate around an outage. There is no risk to the reliability of the grid if planned outages are not studied (by the Transmission Planner) in planning assessments because the outages are studied by Operations Planning.

Some additional points to consider:

- The purpose of the standard TPL-001-4 is to “Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies”. Outages that would be scheduled in the planning horizon would be subject to the performance requirements of this standard. Outages that would be scheduled in the operating horizon should be subject to the performance requirements of other standards.

- Planned maintenance and construction outages typically last from a few days to a few weeks and occur during off-peak time periods with load levels ranging from light load to shoulder peak.

- During the construction and maintenance seasons multiple facilities are out of service at the same time and are studied in the operating horizon.

- System adjustments, including transmission switching and generation redispatch (develop short term operating guides), are made as needed to accommodate planned maintenance and construction outages.

Regarding Item 2b: We believe there is very little risk if stability analysis is not performed for the unavailability of long lead time equipment. If there is an outage of long lead time equipment, system operations will operate around any problem that might be indicated by their analysis. From a stability standpoint this would most likely be a small limitation on the amount of generation at a plant near the outaged element.

Regarding Item 3: No problems are foreseen with updating references relevant to the retirement of MOD-010 and MOD-012.

1. While we agree with the overall purpose and changes to the SAR, applying the single point of failure testing to the entire BES is a significant excess that will likely end up with increased spending and very little reliability benefit. It should only be required to be performed on certain facilities, like those the FERC Order 754 test used. This would limit the testing to facilities with the potential for instability, uncontrolled separation, or cascading outages. We recommend the goal 1 of the SAR be modified to:

"Consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) as identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request", allowing consequential and non-consequential load loss, but not cascading."

In addition, we note that the recent Cost Effectiveness Pilot results show that industry is virtually unanimous in stating that the effect of not considering outages of less than six months is very low risk and and be considered under IRO-017 Outage Coordination. We recommend that goal 2 of the SAR be modified to:

" Address the reliability objectives of the two FERC directives from Order No. 786, which may be able to be accomplished more cost-effectively by considering which, if any, changes are needed to TPL-001, or possibly other NERC standards, such as IRO-017

Table 1 footnote 13 Protection System revisions

First, we recommend that the “and open circuit” revision proposed for Table 1 footnote 13 be omitted or the system performance associated with P5 contigencies be revised, unless it can be demonstrated that the inclusion of this criterion and the existing P5 system performance criteria will significantly improve BES reliability and not lead to unreasonable costs.

Most BES substations have a single DC supply and no open circuit monitoring. So, the new open circuit criterion may result in the identification system performance deficiencies at many substations. The corrective action of adding open circuit monitoring may not be feasible and have an unreasonable cost. The corrective action of adding a dual DC supply may also have an unreasonable cost. The initial cost of adding a redundant DC supply at a single station might cost over $500,000 if there is room in the existing control house and even more if the control house has to be expanded. In addition, there is the ongoing cost of peforming the maintenance and testing required by the NERC PRC-005-6 Relibility Standard.

FERC Order 754 conclusions were based on the criteria of both a significant number of transmission interconnections and a 2000 MW stability impact. So, it is reasonable to expect that the addition of the FERC Oder 754 contingency criteria to the TPL-001 standard should have the same system performance criteria as Order 754.

The reliability benefits of the “and open circuit” revision are may be negligible. According to the 2016 NERC State of Reliability Report, DC systems accounted for 5% of NERC protection systems misoperations between 2011 and 2015. And there is no assertion that the system impacts associated with these protection system misoperations were significant.

Second, we also recommend that the “DC control circuitry” proposed for Table 1 footnote 13 be omitted or the system performance associated with P5 contigencies should also be revised, unless it can be demonstrated that the inclusion of this criterion and the existing P5 system performance criteria will significantly improve BES reliability and not lead to unreasonable costs.

Most BES substations have one set of DC control circuity. So, the new DC control circuity criterion may result in identification system performance deficiencies at many substations. The corrective action of adding dual DC control circuit may have an unreasonable cost for the same reasons noted above for adding a dual DC supply.

Six month threshold for planned maintenance outages

As part of the six-month threshold, the SDT should consider giving Transmission Planners and Planning Coordinators flexibility to evaluate planned outages of less than six month duration in combination with “no load loss” planning events (e.g. P1, P2.1, P3, and selected EHV contingencies). The contingency event combinations would be those that risk the loss of a significant amount of firm load or firm transmission service interruption during system off peak load conditions when these shorter planned outages would typically be scheduled.

Terry BIlke - 2

Answer	No
Document Name	

Comment

MISO believes that planned maintenance outages should be considered in planning for the reliable operation of the BPS. If the planning function does not provide for a robust system with sufficient adequacy to allow each facility an opportunity to be removed from service for planned maintenance during periods when maintenance is typically performed (off-peak) and while simultaneously allowing the system to be operated in a manner that is secure for

N-1 contingencies during the planned outage, the RC outage coordination process could be backed into a corner where they are unable to confidently approve certain maintenance outage requests. Given that a core purpose of planning is to ensure the system is adequate, reliable and robust under future conditions, the need for performing future maintenance of facilities cannot be ignored. However, including only scheduled outages with a 6 month duration or longer will not meet the objective of ensuring the system is adequate to accommodate future maintenance, as this method will not verify that the system will support maintenance of each facility where that facility is required to be removed from service. Therefore, the standard should be revised to remove the 6 month planned outage requirement and instead reinstate the provisions in the previous TPL standard where off-peak planning cases are analyzed to ensure the system is capable of supporting a planned outage for each element of the system while simultaneously being secure for the next contingency.

As we mentioned in our cost-effectiveness survey response, if the TPL-001-4 standard were modified simply by a rule change for processing P6 contingencies during off-peak cases (Load shed would not be allowed as a mitigation measure), simulation of a facility being removed for maintenance and the resulting system satisfying the n-1 reliability criteria could be assessed for any time in the Planning Horizon. So removing the 6 month duration requirement in the current standard (which requires a special simulation and cost to complete) and replacing it with the above modification would be effective and require virtually no additional cost.

Ginette Lacasse - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body

Answer	No
Document Name	

Comment

Seattle City Light SMEs had the following feedback:

Please clarify what components are included in ‘component of a Protection System’. Does this include backup AC and DC protection systems? Does this include a wire and fuses? If redundant relays are fed from a single DC circuit breaker, is it non-redundant? Or are we only speaking of Lock-Out Relays and Aux Relays? Failure of a lockout or aux relays will be interpreted by the tripping relay as a breaker failure, and the trip will be sent out via a different channel. This is modeled in P4.

For Table 1- Steady State & Stability Performance Extreme Events, under the Stability column, No. 2 – The SAR is requesting that four new events are added replacing “a relay failure” with “a component failure of a Protection System”. Once again, if a relay issues a trip, and the fault is not cleared, the breaker failure scheme will operate. These scenarios are currently being studied. What are we trying to address with these new additions?

Need clarification on what a “single point of failure” means with regards to this standard in the larger scheme.

Why does the the planned outage window need to be reduced as this study is included in operations seasonal assessment studies.

Spare transformer consideration is not needed as this is handled with extreme event analysis.

City Light thanks you for taking our comments into consideration.

Comment	

NV Energy suggests that the revised standard include all components of a protection system and not just the components presently proposed under footnote 13. NV Energy feels that the Transmission Planner should consider all protection system components in its study area and determine which non-redundant protection system component would affect their planning area the most and study it. By limiting which protection system component to study, there is a potential reliability gap by not studying an excluded protection system component.

Colby Bellville - 1,3,5,6 - FRCC,SERC,RF, Group Name Duke Energy	
Answer	No
Document Name	
Comment	

At this time, Duke Energy's main concern is to what degree redundancy will be required in the “Protection System,” and what all would be included in the “components” of the Protection System.

If the authors of the new document intend to base their requirements on the definitions of redundancy in the 2008 NERC technical paper titled “Protection System Reliability Redundancy of Protection System Elements”, a large number of “components” and their current state of implementation would have to be examined/reviewed. This could require a significant volume of work/cost to become compliant based on future document requirements. The following are some questions that would need to be answered::

1. Statement: In current state, many protection and control cables run through a single tray and outdoor trench system.

   Questions/Concerns: To address single component failure, would multiple cable trays or divided cable trays be required? This would potentially be a massive effort to address this issue. A separate secondary trench could be difficult to fit into some entities existing designs.

2. Statement: Many control houses are limited in room and panel space. Many legacy transmission designs have used a single panel for the protection and control of either 1 or 2 transmission lines, or a single panel for 2 bus differential designs. Due to space availability, some entities may use two primary differential systems in one panel and a separate shared secondary in another panel.

   Questions/Concerns: Would future requirements would require the use of 2 panel designs (one for primary and one for secondary protection), and would it be required to have such panels physically separated? In conjunction with separate cabling routing requirements, would the panels have to be lined up on separate rows feeding the separate systems? In order to address this type of a requirement, a significant number of control house additions/replacements would be required.

3. Statement: Many legacy designs use a single DC Panel as well as a single DC source to both primary and secondary protection. While newer designs have used 2 DC sources to the protection (one for primary and one for secondary), many existing substations continue to use one DC panel.

Questions/Concerns: It appears that single DC Panel designs would no longer be acceptable, and all of the legacy DC designs that use a single DC sources in conjunction with fuses to separate DCs for primary and secondary protection would no longer meet a “component” redundancy requirement. This could potentially be a huge undertaking to address existing infrastructure should this become a requirement.

4. Statement: There does not appear to be a clear understanding of when redundant batteries would be required OR what would be an acceptable way to monitor substation battery health.

Questions/Concerns: Would the battery monitoring system need to monitor all cells of the battery? In many cases the health of a battery cannot be determined unless the charger is removed and DC load is placed on the battery; would this be a requirement of the monitoring system?

Until acceptable battery monitoring systems are defined, the scope and magnitude of this requirement cannot be determined.

5. Statement: Pilot communications are a “component” of the protection system. It is unclear what is acceptable and what defines a single component of pilot protection communications.

Questions/Concerns: Are two independent fiber optics run through a single static wire considered separate components, or by being in a single static wire are they considered a single point of failure?

If communication multiplexers are used in the pilot protection, would 2 complete separate communication multiplexer boxes be required to meet the redundancy requirement? Would one multiplexer with 2 independent power supplies be acceptable to meet single component failure requirements? Would one multiplexer with using multiple cards for communication be considered redundant?

6. Statement: Carrier equipment is used in many Directional Comparison Blocking (DCB) protective schemes in transmission. Some entities continue the use of carrier equipment as a reliable means of pilot protection, especially where no other pilot communications are available.

Questions/Concerns: What degree of redundancy would be required on systems using power-line carrier? Would multiple frequency tuners and traps be considered n-2 component failures? If installing multiple sets of tuners and traps to achieve full redundancy becomes required, this could be physically difficult to perform, as well as being financially burdensome.

7. Statement: For the carrier schemes, some entities use frequency shift DCUB, POTT, & BFTT which use up additional frequency band requirements. In the case of BFTT (remote breaker failure trip), some only use one carrier channel for both line schemes.

Question: Should the BFTT channel also be redundant in all cases? Should the local and remote Lockout relays also be separated into redundant schemes?

8. Statement: Many breakers and transformers in service have a limited number of CTs available for protection. In many cases the primary and secondary protection share CTs. Sometimes it is physically impossible to add additional CTs to existing breakers and transformers.

Questions/Concerns: If CT failure is evaluated in these protection systems, it would require the replacement of these breakers and transformers. This would have significant financial impacts, and could take many years to address. Are these types of concerns being addressed by the standard drafting team?

Can different adjacent primary differential schemes share the same CT?

9. Statement: Some entities have existing breakers that use a single trip coil.

Questions/Concerns: Would all of the older breakers with one trip coil require replacement? If an older breaker with one trip coil is replaced with a 2 trip coil breaker, would this mandate a complete protection upgrade that would require the use of both trip coils? Is this correct (it would not appear acceptable to operate a single trip coil design with a 2 trip coils available in a newer breaker)?

10. Statement: Many free standing CTs have multiple cores, and many potential transformers have multiple secondary outputs. Catastrophic failure of a single free standing CT could result in the simultaneous loss of many currents to the protective system. While some of the newer protection installations use two potential transformer outputs independently (one voltage to primary and one to secondary), many do not.

Questions/Concerns: If these types of CTs and Potential Transformers are viewed as a "component" of the protective system and a source of multiple simultaneous impacts to both primary and secondary protective systems, significant upgrades and instrument transformer installations would be required to address risks associated with component failure. This could be an overwhelming task to address these type of component failures.

11. Statement: IT requirements and their redundancy requirements on communications are not clear at this time. Questions/Concerns: Some requirements state that monitoring could alleviate the need for redundancy of a component (example- batteries); what redundancy is required in the monitoring component? Do these types of systems require redundancy in power supply and communications?

Comment

Seminole's comments regarding the proposed SAR, its goal(s), and the newly appointed Standard Drafting Team, includes several items for the team's consideration as they review the existing TPL-001-4 standard in light of Order 754 and single points of failure:

1. Order 754, for most entities, resulted in voluminous amounts of coordination and study work for planning and system protection engineers in evaluating single points of failure, even with a limited scope of including only those facilities that met the criteria of Table 1.1 "Buses to be tested." Seminole requests the drafting team strongly consider the impact of changing the word "relay" with "component of protection system" in light of the Order 754 effort, understanding that a Planning Assessment is required under R1 of TPL-001-4 to be completed annually which may equate to entities having to double up on planning staff to fulfill this increased TPL scope due to what appears to be a harmless word change.

2. If a change is made as a result of the drafting team review, Seminole requests that the drafting team give strong consideration of including a criteria for which buses need to be evaluated as part of the "annual Planning Assessment" for single points of failure, similar to the criteria used in Order 754 rather than using subjective terminology such as "that create the most severe impact."

Seminole requests the following additional item as part of the drafting team scope:

Evaluate R1 of TPL-001-4 to determine what portions of R1 can be removed/retired in light of the newly enforceable MOD-032 standard.

Comment	

- Table 1 footnote 13 Protection System revisions

First, I recommend that the “and open circuit” revision proposed for Table 1 footnote 13 be omitted or the system performance associated with P5 contingencies be revised, unless it can be demonstrated that the inclusion of this criterion and the existing P5 system performance criteria will significantly improve BES reliability and not lead to unreasonable costs.

Most BES substations have a single DC supply and no open circuit monitoring. So, the new open circuit criterion may result in the identification system performance deficiencies at many substations. The corrective action of adding open circuit monitoring may not be feasible and have an unreasonable cost. The corrective action of adding a dual DC supply may also have an unreasonable cost. The initial cost of adding a redundant DC supply at a single station might cost over $500,000 if there is room in the existing control house and even more if the control house has to be expanded. In addition, there is the ongoing cost of performing the maintenance and testing required by the NERC PRC-005-6 Reliability Standard.

FERC Order 754 conclusions were based on the criteria of both a significant number of transmission interconnections and a 2000 MW stability impact. So, it is reasonable to expect that the addition of the FERC Oder 754 contingency criteria to the TPL-001 standard should have the same system performance criteria as Order 754.

The reliability benefits of the “and open circuit” revision are may be negligible. According to the 2016 NERC State of Reliability Report, DC systems accounted for 5% of NERC protection systems misoperations between 2011 and 2015. And there is no assertion that the system impacts associated with these protection system misoperations were significant.

Second, I also recommend that the “DC control circuitry” proposed for Table 1 footnote 13 be omitted or the system performance associated with P5 contingencies should also be revised, unless it can be demonstrated that the inclusion of this criterion and the existing P5 system performance criteria will significantly improve BES reliability and not lead to unreasonable costs.

Most BES substations have one set of DC control circuity. So, the new DC control circuity criterion may result in identification system performance deficiencies at many substations. The corrective action of adding dual DC control circuit may have an unreasonable cost for the same reasons noted above for adding a dual DC supply.

- Six month threshold for planned maintenance outages

I have some concerns in reference to some of the proposed changes in the SAR. As I stated in my comments for the Cost Effectiveness Pilot SAR (TPL-001-4) in reference to the six (6) month threshold, “I feel by removing the six (6) month threshold, FERC opens the door to annual TPL-001-4 planning assessments being performed for one day outages. Short term outages are considered in operational planning assessments such as seasonal, next-day, and current-day assessments". Additionally, I would be concerned that if I include outages less than 6 months that I might be putting multiple outages in the model that might not really overlap (e.g. 2 one month outages that are planned to be in succession may have to both be in the model shown as being outaged). At this point, I will make the assumption that the 'Cost Effectiveness Pilot' data will serve as support in reference to the concerns in FERC Order 786 pertaining to Paragraph 40 six (6) month threshold issues. With that being said, I would suggest that the drafting team take that the industry's feedback into consideration in reference to the 'Cost Effectiveness Pilot Project' into this current project moving forward.

- Spare equipment strategy for steady state analysis

As for the newly proposed language pertaining to Spare Equipment Strategy for TPL-001-4, I would suggest that the drafting team create an additional requirement for this topic and include it the Standard. I feel adding this language into one of the existing requirements will only cause confusion for the industry. Additionally, I feel that the drafting team needs to implement the proposed language in reference to Spare Equipment Strategy in a new subsection in Requirement 2 section 2.4. This would tie it to Requirement 4 section 4.4 which would lead to the industry developing a contingency list expected to produce more severe system impacts for this stability Spare Equipment Strategy Analysis. Additionally, I would suggest adding some rationale language to help explain the drafting team's intents for the proposed language as well as addressing FERCs concerns in reference to Paragraph 89.

- Updating the MOD references

Finally, I agree with the modification to Requirement R1 pertaining to the retirement of MOD-10 and MOD-12 Standards. The Implementation Plan and the modification reflects consistency with the proposed modification suggested in the Standards Authorization Request (SAR).

PacifiCorp supports changes to the draft SAR as listed in 1) and 3) above. However, PacifiCorp does not support the change in change 2): **2a.)** Planned maintenance outages of less than six months in duration are not necessary for long-term annual planning assessments such as TPL-001-4. The annual TPL-001-4 assessments which look in the near-term (years 1 – 5) and long-term (years 6 – 10) planning horizons are reasonable projections of system conditions and are not meant to represent the specific operational type concerns for outages shorter than six months. Risk is based on probability, duration, and severity. The probability and duration of outages less than six months reduces the chance of an event towards zero as the duration gets smaller. Therefore, the industry reviewed and approved six month duration threshold is appropriate for a planning assessment. By removing the six month threshold, FERC opens the door to annual TPL-001-4 planning assessments being performed for one day outages such as those required for mandated PRC-005-2 relay and maintenance testing. Short term outages are considered in operational planning assessments such as seasonal, next-day, and current-day assessments. Annual Planning Assessments are not operational assessments. In short, annual planning assessments become meaningless as durations become shorter than six months. An annual TPL-001-4 planning assessment represents a reasonable general snapshot of the system assuming all equipment is available and in-service except for the specific contingency performed. Daily operational conditions almost never have the system entirely intact and available due to necessary system maintenance and testing. With respect to the concern for evaluation of planned maintenance outages in the seasonal off-peak periods, inclusion of a requirement to perform an assessment of the off-peak seasonal case for planned maintenance outages with durations greater than six months in duration, that extend into seasonal off-peak periods, may be appropriate for the TPL planning assessment. **2b.)** While stability analysis of equipment with a higher probability of complete failure (transformers, circuit breakers) in the absence of spare inventory may identify practical system risks, stability analysis on equipment with significantly lower probabilities of complete failure (series and shunt capacitors, series and shunt reactors, dynamic reactive support), for which maintaining a spare inventory is impractical, may unnecessarily identify deficiencies that have an exceptionally low risk of occurrence. PacifiCorp recommends NERC complete efforts on the Cost Effectiveness Pilot-2016 to establish a reasonable and supportable threshold for the types of equipment that should be subject to the spare equipment requirement based on probability of failure or some other metric to be determined. PacifiCorp believes that implementation of Order 786, paragraph 89, requiring stability assessment of all equipment with a lead time of one year or more without regard to probability of failure would result in significant administrative, capital and operations and maintenance costs without reasonable justification of the reliability benefit that would be realized by those costs. Specifically, maintaining spare inventory for reactive devices with a low probability of failure would create a significant cost burden on utility ratepayers nationwide. Many of these reactive support devices are custom designed and a complete spare would have a high cost for a minimal system reliability benefit.

Regarding Item 1:	

TVA believes changing “address” to “consider” would not align with the recommendations of the SPCS and SAMS. The word “consider” may allow for open interpretation of those recommendations resulting in an increase of scope beyond that which is practical.

While the original FERC Order 754 work was performed with a focus on EHV facilities, there is no language in the SAR that would appear to limit the additional scope of this work in the TPL-001-4 standard to only EHV facilities, for which protection system issues would presumably have a more widespread impact to the BES. We believe the original intent of Order 754 to target EHV Facilities is a proper allocation of resources in order focus attention on Facilities with the most significant impact to the BES.

TVA asks the SPCS and SAMS to poll the industry for cost estimates to implement all work required as a result of making these proposed changes to the TPL-001-4 standard. Requiring redundancy of protective relays as well as DC systems could result in significant facility upgrades, including the construction of a new switch house, for all facilities failing to meet planning criteria. The costs associated with these corrective action plans could significantly outweigh the benefits of protecting against these low probablility events.

Regarding Item 2a:

Planned maintenance outages are considered in operational planning studies which assess the reliable operation of the BPS. Multiple contingency studies for off-peak conditions which consider maintenance outages for a single element plus the subsequent unplanned loss of an additional single element are included in TPL-001-4. These studies support system reliability, system maintenance, and operational flexibility. Moreover, additional transmission studies including planned maintenance outages would typically overlap with operational studies. Therefore, TVA sees a low risk to the reliable operation of the BPS if planned maintenance outages of less than six months duration are not considered in TPL-001-4 studies.

Regarding Item 2b:

If the unavailability of long lead-time equipment is not considered in stability analysis for P0, P1 and P2 events, there is a risk of detrimental impacts to BPS reliability. Generally, the unavailability of long lead-time equipment studied under P0 will be bounded by the existing P1 studies. The unavailability of long lead-time equipment studied under P1 and P2 may not be considered completely bounded by any existing studies. However, given the scope of contingency events already considered, it would be unlikely that critical events would be missed. Therefore, TVA sees a low risk to the reliable operation of the BPS if the unavailability of long lead-time equipment is not considered in stability analysis for P0, P1 and P2 events.

Regarding Item 3:

TVA sees no issues with updating references.

Comment

The omission of significant BES outages lasting less than six months from studies as part of the required annual Planning Assessment in accordance with TPL-001-4 is a low risk reliability concern due to Operation Horizon studies and Outage Coordination (IRO-017). However, a slight modification of R1.1.2 is recommended to state: “Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months, or with a duration of less than six months selected by engineering judgment.” This small change addresses the perceived reliability concern by codifying current industry practice and grants the flexibility for study performance to the Transmission Planner.

Our review group has some concerns in reference to some of the proposed changes in the SAR. As we stated in our comments for the Cost Effectiveness Pilot SAR (TPL-001-4) in reference to the six (6) month threshold, “we feel by removing the six (6) month threshold, FERC opens the door to annual TPL-001-4 planning assessments being performed for one day outages. Short term outages are considered in operational planning assessments such as seasonal, next-day, and current-day assessments”. Additionally, we would be concerned that if we include outages less than 6 months that we might be putting multiple outages in the model that might not really overlap (e.g. 2 one month outages that are planned to be in succession may have to both be in the model shown as being outaged). At this point, we will make the assumption that the ‘Cost Effectiveness Pilot’ data will serve as support in reference to the concerns in FERC Order 786 pertaining to Paragraph 40 six (6) month threshold issues. With that being said, we would suggest that the drafting team take that the industry’s feedback into consideration in reference to the ‘Cost Effectiveness Pilot Project’ into this current project moving forward.

As for the newly proposed language pertaining to Spare Equipment Strategy for TPL-001-4, we would suggest that the drafting team create an additional requirement for this topic and include it the Standard. We feel adding this language into one of the existing requirements will only cause confusion for the industry . Additionally, the review group feel that the drafting team needs to implement the proposed language in reference to Spare Equipement Strategy in a new subsection in Requirement 2 section 2.4. This would tie it to Requirement 4 section 4.4 which would lead to the industry developing a contingency list expected to produce more severe system impacts for this stability Spare Equipment Strategy Analysis. Additionally, we would suggest adding some rationale language to help explain the drafting team’s intents for the proposed language as well as addressing FERCs concerns in reference to Paragraph 89.

Finally, we agree with the modification to Requirement R1 pertaining to the retirement of MOD-10 and MOD-12 Standards. Our group reviewed the Implementation Plan and the modification reflects consistency with the proposed modification suggested in the Standards Authorization Request (SAR).

(a) Paragraph 40 Directive

The ISO/RTO Council (SRC) Standards Review Committee (SRC) acknowledges that the SDT must address the two outstanding directives from FERC Order No. 786. However, revising TPL-001-4 to address these two directives is unnecessary.

First, Order No. 786 directs NERC to address the concern that excluding planned maintenance outages less than six months in duration in the TPL-001-4 assessment could potentially impact bulk electric system reliability. The SRC agrees that planned maintenance outages should be considered in planning for the reliable operation of BPS. However, outages less than six months in duration discussed in the FERC order are already accounted for in grid planning during the outage coordination process in the operational planning horizon.

Reliability Coordinators (RCs) consider requests for planned maintenance outage submitted by entities in their respective RC areas through their outage coordination procedures. Each RC presently has the authority to deny any planned maintenance outages that would create reliability risks and thereby mitigate any potential risks resulting from planned maintenance outages in its RC area. Reliability Standard IRO-017-1 – *Outage Coordination*, effective April 1, 2017, codifies this practice by requiring RCs to establish a generation and transmission outage coordination process. Consequently, there is no risk to the reliable operation of the BPS if planned maintenance outages of less than six months in duration are not considered in planning studies during one or both seasonal off-peak periods under the TPL-001-4 standard. Also, even if these outages weren't already managed through outage coordination, requiring planners to consider them in transmission planning studies may not be helpful anyway, since a significant number of planned maintenance outages conducted in any given year will not be scheduled or submitted for approval far enough in advance to be incorporated into the planning assessment required under TPL-001-4.

Furthermore, requiring planners to study these outages could result in the identification of costly transmission upgrades to address needs that are expected to be temporary. For this reason, outage coordination is a much more cost-effective option for addressing these outages.

The SRC recommends that the SDT address FERC's directive in Order 786 by requiring that Transmission Planners and Planning Coordinators evaluate planned maintenance outages of less than six months in duration only if the RC for the RC area in which the facilities subject to the Planning Assessment are located does not already coordinate outages for those facilities.

(b) Paragraph 89 Directive*

Second, Paragraph 89 in Order No. 786 directs NERC to "consider" whether it should modify TPL-001-4 to include potential outages of long-lead-time equipment in stability analyses for the P0, P1 and P2 categories identified in Table 1. A revision to TPL-001-4 to address this concern is unnecessary because TPL-001-4 already requires entities to perform stability analyses for the P3 through P7 categories, which produce the same contingency results that stability analyses for P0 and P1 categories would produce assuming unavailability of long-lead-time equipment. While SRC acknowledges that stability analyses of P3 through P7 conditions do not currently include the multiple contingency loss of long-lead-time equipment coupled with the fault conditions described in P2, requiring these additional stability analyses would not be cost-effective because these conditions have historically been very infrequent. For this reason, it is unnecessary and inappropriate to require the proposed analysis.

(c) Single Points of Failure

While we agree with the overall purpose and changes to the SAR, applying the single point of failure testing to the entire BES is a significant excess that will likely end up with increased spending and very little reliability benefit. It should only be required to be performed on certain facilities, like those the FERC Order 754 test used. This would limit the testing to facilities with the potential for instability, uncontrolled separation, or cascading outages. We recommend the goal 1 of the SAR be modified to: “Consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) as identified in the SPCS and SAMS report titled “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request”, allowing consequential and non-consequential load loss, but not cascading.”

*The IESO does not sign on to the comments addressing the Paragraph 89 directive.

** Please note that MISO and CAISO do not sign on to these comments.

MidAmerican supports the MRO NSRF comments in general with the following additions.

We recommend that the “and open circuit” revision proposed for Table 1 footnote 13 be omitted or the system performance associated with P5 contigencies be revised unless it can be demonstrated that the inclusion of this criterion and the existing P5 system performance criteria will significantly improve BES reliability and not lead to unreasonable costs. NERC needs to clearly articulate the BES risk being addressed with the "open circuit" battery monitoring and / or the dual battery banks. If the risk is related to battery capacity, then a dual battery bank mandate may be costly and may not correct the issue. If the risk is an open battery circuit, the open circuit presents a significant risk, and the open circuit monitoring corrects that risk, then the proposal may be appropriate. The reliability benefits of the “and open circuit” revision for battery monitoring may be negligible. According to the 2016 NERC State of Reliability Report, DC systems accounted for 5% of NERC protection systems misoperations between 2011 and 2015 and there is no assertion that the system impacts associated with these protection system misoperations were significant.

We recommend that the “DC control circuitry” proposed for Table 1 footnote 13 be omitted or the system performance associated with P5 contigencies should also be revised, unless it can be demonstrated that the inclusion of this criterion and the existing P5 system performance criteria will significantly improve BES reliability and not lead to unreasonable costs.

Most BES substations have one set of DC control circuity. Recent State of Reliability report did not articulate what impact DC control circuits have on misoperations, so the corrective action of adding dual DC control circuit may have an unreasonable cost for little to no benefit.

We recommend that removing the six-month TPL-001-4 planning assessment threshold is not cost effective and the FERC directive in paragraph 40 of Order No. 786 relating to TPL [illegible] equally effective alternative be proposed to address FERC’s concerns about off-peak conditions. Existing wording in the NERC standard could be identified or clarified to state "outages of more than six-months should include a sensitivity analysis if the outage occurs in the spring and / or fall months."

By removing the six month threshold, FERC opens the door to annual TPL-001-4 planning assessments being performed for one-day outages such as those required for mandated PRC-005-2 relay and maintenance testing. Short term outages are considered in operational planning assessments such as seasonal, next-day, and current-day assessments. Annual Planning Assessments are not operational assessments. In short, annual planning assessments become meaningless as durations become shorter than six months. An annual TPL-001-4 planning assessment represents a reasonable general snapshot of the system assuming all equipment is available and in-service except for the specific contingency performed. Daily operational conditions almost never have the system entirely intact and available due to necessary system maintenance and testing.

Comment	

The IESO generally agrees with the proposed changes to the scope of the SAR. Nevertheless, as indicated in our comments on the previous SAR, some of the proposed changes to TPL-001-4 described in the SAR are unclear. Hence, we reserve our judgment on the final scope and the specific changes that will be made to the TPL-001-4 standard. For example:

1. **The replacement of FN 13 with the proposed wording but there is no mention of the placement of the functions or types of relay that will be replaced.**
2. **The meaning of “evaluation of the three-phase faults the described component failures of a Protection System” in the last bulleted proposed change is unclear. Does it mean evaluation of a three phase fault combined with the component failure of a Protection System? This needs to be clarified.**
3. **The SAR is unclear on the fault locations that need to be assessed to meet the following objective:**

“Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults with the described component failures of a Protection System13 that produce the more severe system impacts.

Generally, in planning studies, the three-phase faults that are assessed are located on the buses or in their vicinity on the circuits since they have more severe system impact. These faults can still be cleared remotely while the local protection systems experience a component failure.

When the three-phase faults are moved along the circuits there may be locations where the faults remain un-cleared since the protection systems (including the back-up ones) may not be able to detect the faults while they experience a component failure.

Is the intention of the SAR to identify the fault locations where the three-phase faults will remain un-cleared while the protection systems experience a component failure?

The IESO would appreciate the final SAR having more clarity on the above issues.

Comment	

AEP considers the perceived risk of not considering planned maintenance outages less than six months in duration in its studies to be minimal (as previously stated in our comments for the Cost Effectiveness Pilot). At present, our Operations team (in conjunction with applicable RCs) addresses these short duration issues in both real time and seasonal analysis. It would be impractical to address short duration maintenance outages as part of long term planning and modeling. As a result, we do not believe there is a risk-based need to adjust the threshold to less than six months in system models.

As stated in our comments for the previous comment period on this project, the SDT should emphasize both feasibility and practicality in any future requirements regarding system modeling, and the implementation thereof.

Use of the term “include” in the revised footnote 13 may be a source of confusion about whether the other two Protection System components (communication systems, voltage and current sensing devices) are also required by the TPL standard. Rather than “include, we recommend instead using “are” in the revised footnote 13.

We would further recommend not qualifying a NERC Glossary term by footnoting the term “Protection System.” It would be preferable to simply state which components are applicable in Table 1 itself.

While “Single Point of Failure” may have been the original driver for this project, the directives within the SAR now appear to be fairly diverse. Because of this widened scope, the SDT may wish to consider adopting a new project title, one that more clearly specifies their objectives.

The recent comment period for the Cost Effectiveness Pilot for Project 2015-04 (TPL-001-4) included the following guidance: “Project 2015-10: Single Points of Failure TPL-001 from the 2016-2018 Reliability Standards Development Plan is developing a SAR to address potential modifications to TPL-001-4. The results of this pilot will be provided to the drafting team to inform their work on modifying this standard.” The due date for comments for Project 2010-04 was 5/26, which turned out to also be the kickoff date for Project 2015-10. How is it possible that comments for Project 2015-04 could be used to further develop the Project 2015-10 SAR, given that there were no calendar days separating the two comment periods?

Comment

CenterPoint Energy agrees the two (2) outstanding FERC directives from FERC Order No. 786 should be addressed; however, CenterPoint Energy believes the Standard Drafting Team can address the two directives in other ways than modifying Reliability Standard TPL-001-4. CenterPoint Energy comments submitted for the Cost Effectiveness Pilot related to this project included the following:

- CenterPoint Energy does not see risks associated with the current six-month threshold for modeling known outages of generation or Transmission Facility(ies) as specified in TPL-001-4 R1.1.2. Planned maintenance outages of generation or Transmission Facility(ies) with a duration of at least six months are rarely, if ever, scheduled far enough in advance to be included in the Near-Term Transmission Planning Horizon. Shortening the timeframe would only decrease the likelihood of identifying a relevant outage. However, TPL-001-4 R2.1.4 allows for sensitivity analysis to be performed for outages less than six months in duration. If such outages are deemed potentially critical to system reliability, they may be included in the assessment under the current Standard. Furthermore, outages of less than six months reflect operational scenarios and are considered in required operational planning assessments.

- CenterPoint Energy does not believe there is any risk because the impact of the unavailability of long lead time equipment for TPL-001-4 Category P0, P1 and most P2 conditions is already captured as part of the Category P6 stability analysis.

Comment

While Texas RE believes that the scope of the proposed project set forth in the revised SAR appropriately includes the SPSC and SAMS recommendations contained in the Order No. 754 Assessment of Protection System Single Points of Failure report and the FERC directives from FERC Order No. 786, Texas RE remains concerned that the overall scope of this project is too limited. Specifically, Texas RE supports those commenters, such as XCEL, that have suggested that the scope of this project include consideration of any significant issues, reliability gaps, and policy concerns identified through the implementation of the existing TPL-001-4 Standard. Texas RE requests the SDT consider areas in which the existing Standard can be improved, clarified, or expanded as necessary to address reliability issues as they are identified throughout the course of this project.

Consistent with this comprehensive look at the TPL-001-4 Standard, Texas RE also urges the SDT to consider the impact of changes in this Standard on other requirements and definitions. Texas RE previously submitted the comment that it is concerned the proposed language for footnote 13 in TPL-001-4 does not match the NERC Glossary term for Protection System. The language proposed in the SAR for “protective relays” and “DC control circuitry" largely tracks the definition of "Protection System" set forth in the NERC Glossary of Terms. The sole substantive distinction appears to be limiting the general category of "control circuitry" explicitly to "DC control circuitry" consistent with recommendation in the Order No. 754 Report.

In contrast, the SAR (and the Order No. 754 Report) places additional, qualifying language on the definition of "station DC supply" that is not contained in the definition of Protection System in the NERC Glossary of Terms. Specifically, the "Protection System" definition in the NERC Glossary of Terms includes: "Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery based dc supply)." The SAR (and the recommended language in Order No. 754 Report) qualifies this language by describing "station DC supply" as "single-station DC supply that is not monitored (i.e., not reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated)."

Texas RE recommends that the SDT use of the existing definition of station DC Supply in the NERC Glossary of Terms. Using consistent language in both Standards would help entities classify their dc supply components in a uniform manner across their compliance program.

Comment

(1) We generally agree with the expanded scope and intent of this project, particularly with the modification to requirements and Violation Severity Levels associated with the retirement of MOD-10 and MOD-12 standards. However, there still remains ambiguity in the attributed compliance responsibilities between Planning Coordinators and Transmission Planners in this standard. We recognize the necessary coordination between both functional roles, although clarification should be added to define which functional role is responsible.

(2) We have concerns regarding interpretations of the two directives in Order No. 786 meant to address 1) additional contingency studies to include protection components as "spare equipment," and 2) changes to the six-month threshold to include planned maintenance outages of significant facilities in future planning assessments. There is concern that by removing the six-month threshold, operational planning assessments may be required and create a substantial cost burden on the industry. We ask the SDT to refer to industry feedback associated with the "Cost Effectiveness" project when developing this aspect of the standard and provide sufficient clarification around planning assessment expectations. Regarding studies that include a spare equipment strategy component, we believe the SDT should limit their response to the directive to only substation power transformers before including other BES Elements. Moreover, we believe the SDT should incorporate this additional component in a new requirement and avoid the revision of existing stability analysis requirements.

(3) We sustain our previous concerns that the current applicability of this standard is inclusive to all BES Elements, not the sub-set identified and analyzed as part of the Section 1600 Data Request. The findings identify that buses under 300 kV are less likely to result in an adverse impact to BES reliability based from a Protection System single point of failure. Proposing to collect data for all BES Elements poses an unnecessary administrative burden on registered entities and their models, especially considering that the findings do not support additional analysis under 300 kV. Moreover, analysis results identifying issues which adversely impact the BES reliability could be masked by insignificant concerns.

(4) Within the proposed SAR, we identify several misspellings with words like "consideration" or "cited," and alert the SDT to correct these errors prior to NERC Standards Committee approval.

(5) We thank you for your time in developing this revision to the SAR and the opportunity to provide these comments.

Consideration of Comments

Project 2015-10 (TPL-001-4) Single Points of Failure

Executive Summary

The Project 2015-10 Standards Authorization Request (SAR) drafting team (DT) thanks everyone who submitted comments on the TPL-001-4 SAR. The SAR was posted for an additional 30-day informal comment period from May 26, 2016, through June 24, 2016. The reason it was posted a second time was to provide industry with the expanded scope of the SAR, which added the two outstanding FERC directives from FERC Order No. 786 and to update the MOD references in the TPL standard.

Comments received covered the System Protection and Control Subcommittee (SPCS) and System Analysis and Modeling Subcommittee (SAMS) Report of FERC Order No. 754, the two FERC directives from Order No. 786, updating the MOD references, a couple of errata changes to the SAR, and a few miscellaneous questions. The SAR DT had a conference call on June 30, 2016, to discuss comments received. The SAR DT made a few minor errata type changes (spelling corrections and moved a couple of sentences around to provide clarity to the purpose of the SAR). In conclusion to the SAR DT conference call, the SAR DT determined that the SAR would be considered final. A redline and clean version of the final SAR are posted on the project page.

There were a good amount of comments received providing justification for the directives, etc. Those comments will be passed to the standards drafting team (SDT) for consideration. Comments received that were not added to the scope of this project, will be addressed during the enhanced periodic review of this standard.

Summary of Comments Received

Below provides a high level summary of comments received for project 2015-10 Single Points of Failure SAR, and the SAR DTs responses. Due to the comment period being informal, the SAR DT is not required to response to comments. The SAR DT thanks everyone for their time and effort in submitting comments.

SPCS and SAMS Report – FERC Order No. 754

Multiple commenters were concerned with the wording change from “address” to “consider” in regards to the SPCS/SAMS report recommendations. The comments suggested that the SDT should follow the recommendation identified and documented by SPCS/SAMS report and that further “consideration” by the SDT is not necessary to meet the FERC directives. There were also comments that included recommendations for changes in specific SPCS/ SAMS recommendations.

The SAR DT concluded that leaving the word “consider” in the SAR would allow the SDT to consider all comments received.

FERC Order No. 786 – Two FERC Directives

The purpose of the SAR DT was to develop the scope for Project 2015-10. The SAR DT concluded that the two FERC directives need to remain a part of the scope, whether that is addressing the directives, providing an equally efficient and effective alternative, or providing justification as to why the directive has already been addressed or is no longer needed. In addition to these three options, FERC directed NERC to consider spare equipment. While some commenters argued that this is not a directive, it is a directive that needs discussion/consideration and a response provided to the Federal Energy Regulatory Commission (FERC).

Spare Equipment Directive:

Many commenters stated that there is very little risk or no risk if stability analysis is not performed for the unavailability of long lead time equipment. The reasoning was based on the following factors: if there is an outage of long lead time equipment, system operations will operate around any problem that might be indicated by their analysis, that the impact of the unavailability of long lead time equipment for TPL-001-4 Category P0, P1 and most P2 conditions is already captured as part of the Category P6 stability analysis, and/or because TPL-001-4 already requires entities to perform stability analyses for the P3 through P7 categories, which produce the same contingency results that stability analysis for P0 and P1 categories would produce assuming unavailability of long-lead-time equipment.

Several commenters had suggestions if the Standard Drafting Team pursued making changes suggested by the directive:

- NERC should complete efforts on the Cost Effectiveness Pilot-2016 to establish a reasonable and supportable threshold for the types of equipment that should be subject to the spare equipment requirement based on probability of failure or some other metric to be determined. Requiring stability assessment of all equipment with a lead time of one year or more without regard to probability of failure would result in significant administrative, capital and operations and maintenance costs without reasonable justification of the reliability benefit that would be realized by those costs.
- As for the newly proposed language pertaining to Spare Equipment Strategy for TPL-001-4, if implemented, suggest that the drafting team create an additional requirement for this topic and include it the Standard in a new subsection in Requirement 2 section 2.4. It is felt that adding this language into one of the existing requirements will only cause confusion for the industry and it would tie it to Requirement 4 section 4.4 which would lead to the industry developing a contingency list expected to produce more severe system impacts for this stability Spare Equipment Strategy Analysis.
- The SDT should limit their response to the directive to only substation power transformers before including other BES Elements.

Duration less than 6 months directive:
Many comments stated that operational studies are already being performed in seasonal assessments, current day and next day studies.

Many comments quoted IRO-017-1, which will be enforceable April 1, 2017; IRO-017-1 R4 requires the Planning Coordinator and Transmission Planner (not TOP) develop solutions for identified issues or conflicts resulting from planned outages in its Planning Assessments for the Near-Term Planning Horizon.

In addition, other comments received indicated the team should consider the following: 1) many comments believed that outages lasting one day would be inappropriate, 2) should off-peak studies be the only seasons required for outage studies, 3) coincide with IRO-017-1 R4, should the outage studies be only in the Near-Term Planning Horizon, and address which planning events have to be included in the outage studies. Example: P1, P2.1, P3 and select EHV planning events.

The SAR DT appreciates all comments received and will ensure the SDT (once formed) receives these comments for consideration.

MOD References

There was general consensus about updating the references to MOD-010 and MOD-012 in Requirement R1 needing to be replaced with MOD-032 due to July 2016 retirement of those standards.

Cost Effectiveness Survey

Many commenters pointed to comments submitted for the cost effectiveness survey. The SAR DT will ensure that the SDT receives all responses for consideration during the modification of TPL-001-4.

NERC welcomes suggestions for improving the reliability of the Bulk-Power System through improved Reliability Standards. Please use this form to submit your proposal for a new NERC Reliability Standard or a revision to an existing standard.

Request to propose a new or a revision to a Reliability Standard			
Proposed Standard:	Project 2015-10 Single Points of Failure TPL-001 SPCS and SAMS recommendations in response to FERC Order No. 754 (TPL-001-4)		
Date Submitted:	October 05, 2015		
SAR Requester Information			
Name:	Philip B. Winston, PE and John M Simonelli		
Organization:	Southern Company and ISO New England, Inc., respectively.		
Telephone:	404-608-5989--primary	E-mail:	pbwinsto@southernco.com--primary
SAR Type (Check as many as applicable)			
☐ New Standard		☐ Withdrawal of existing Standard	
☒ Revision to existing Standards		☐ Urgent Action	

SAR Information
Industry Need (What is the industry problem this request is trying to solve?):
Modifications have been recommended to Reliability Standard TPL-001-4 based on the following: Item 1: The System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) conducted a comprehensive assessment of the study of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section

SAR Information

1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.
As such, regarding single points of failure in protection systems, the SPCS and the SAMS make the following recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process identified in the NERC Rules of Procedure:
 	
• For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
    ▪ Replace “relay” with “component of a Protection System,” and
    ▪ Add superscript “13” to reference footnote 13 for the replaced term under the “Category” column.
• For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
    ▪ Remove the phrase “or a relay failure[13]” from items a, b, c, and d to create distinct events only for stuck breakers.
    ▪ Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing “a relay failure[13]” with “a component failure of a Protection System[13].”
• Replace footnote 13 in TPL-001-4 with, “The components from the definition of “Protection System” for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single-station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.”[1]
• Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults with the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads “[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2.”

[1] See Order 754 (NERC website) Requests for Clarifications and Responses (http://www.nerc.com/pa/Stand/Order%20754%20DL/Order_754-Requests_for_Clarification_and_Responses_July2013.pdf).

SAR Information
Item 2: Further, references to MOD-010 and MOD_012 in Requirement R1 would need to be replaced with MOD-032 due to July 2016 retirement of those standards. In addition, on October 17, 2013 the Commission issued Order No. 786, which included two directives related to TPL-001-4. The two directives are as follows: • Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six-month threshold could exclude planned maintenance outages of significant facilities from future planning assessments • Paragraph 89 directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4."
Purpose or Goal (How does this request propose to address the problem described above?):
The goal of this SAR is to: 1. Consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) as identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request"; 2. Address the two FERC directives from Order No. 786; and 3. Update the references to the MOD Reliability Standards in TPL-001.
Identify the Objectives of the proposed standards' requirements (What specific reliability deliverables are required to achieve the goal?):
Provide clear, unambiguous requirements and Results-based Reliability Standards that will: (1) reflect consideration of the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request;" (ii) address the two FERC directives from Order No. 786 cited above; and (iii) and update the references to the MOD Reliability Standards cited in TPL-001.
Brief Description (Provide a paragraph that describes the scope of this standard action.)
The SDT shall consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request", address the two FERC directives, update the references to the MOD Standards, and

SAR Information
revise standards, requirements, attachments, Violation Risk Factors, Violation Severity Levels, and implementation plans as appropriate. The SDT shall consider retirements to requirements under Paragraph 81 criteria. In addition, the SDT shall work with compliance on an accompanying RSAW to address each of the standard's requirements and measures.
Detailed Description (Provide a description of the proposed project with sufficient details for the standard drafting team to execute the SAR. Also provide a justification for the development or revision of the standard, including an assessment of the reliability and market interface impacts of implementing or not implementing the standard action.)
The SDTs execution of this SAR requires the SDT to consider the recommendations for modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) identified in the SPCS and SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request." This report is incorporated in its entirety into this SAR so as not to unnecessarily repeat or paraphrase the substance of the report. In addition, the SDTs execution of this SAR would consider retirements to requirements under Paragraph 81 criteria.

Reliability Functions	
The Standard will Apply to the Following Functions (Check each one that applies.)	
☐ Regional Reliability Organization	Conducts the regional activities related to planning and operations, and coordinates activities of Responsible Entities to secure the reliability of the Bulk Electric System within the region and adjacent regions.
☐ Reliability Coordinator	Responsible for the real-time operating reliability of its Reliability Coordinator Area in coordination with its neighboring Reliability Coordinator's wide area view.
☐ Balancing Authority	Integrates resource plans ahead of time, and maintains load-interchange-resource balance within a Balancing Authority Area and supports Interconnection frequency in real time.
☐ Interchange Authority	Ensures communication of interchange transactions for reliability evaluation purposes and coordinates implementation of valid and balanced interchange schedules between Balancing Authority Areas.
☒ Planning Coordinator	Assesses the longer-term reliability of its Planning Coordinator Area.
☐ Resource Planner	Develops a >one year plan for the resource adequacy of its specific loads within a Planning Coordinator area.
☒ Transmission Planner	Develops a >one year plan for the reliability of the interconnected Bulk Electric System within its portion of the Planning Coordinator area.
☐ Transmission Service Provider	Administers the transmission tariff and provides transmission services under applicable transmission service agreements (e.g., the pro forma tariff).
☐ Transmission Owner	Owns and maintains transmission facilities.

Reliability Functions		
☐	Transmission Operator	Ensures the real-time operating reliability of the transmission assets within a Transmission Operator Area.
☐	Distribution Provider	Delivers electrical energy to the End-use customer.
☐	Generator Owner	Owns and maintains generation facilities.
☐	Generator Operator	Operates generation unit(s) to provide real and reactive power.
☐	Purchasing-Selling Entity	Purchases or sells energy, capacity, and necessary reliability-related services as required.
☐	Market Operator	Interface point for reliability functions with commercial functions.
☐	Load-Serving Entity	Secures energy and transmission service (and reliability-related services) to serve the End-use Customer.

Reliability and Market Interface Principles	
Applicable Reliability Principles (Check all that apply).	
☒	1. Interconnected bulk power systems shall be planned and operated in a coordinated manner to perform reliably under normal and abnormal conditions as defined in the NERC Standards.
☒	2. The frequency and voltage of interconnected bulk power systems shall be controlled within defined limits through the balancing of real and reactive power supply and demand.
☒	3. Information necessary for the planning and operation of interconnected bulk power systems shall be made available to those entities responsible for planning and operating the systems reliably.
☐	4. Plans for emergency operation and system restoration of interconnected bulk power systems shall be developed, coordinated, maintained and implemented.
☐	5. Facilities for communication, monitoring and control shall be provided, used and maintained for the reliability of interconnected bulk power systems.
☐	6. Personnel responsible for planning and operating interconnected bulk power systems shall be trained, qualified, and have the responsibility and authority to implement actions.
☐	7. The security of the interconnected bulk power systems shall be assessed, monitored and maintained on a wide area basis.
☐	8. Bulk power systems shall be protected from malicious physical or cyber attacks.

Reliability and Market Interface Principles	
Does the proposed Standard comply with all of the following Market Interface Principles?	Enter (yes/no)
1. A reliability standard shall not give any market participant an unfair competitive advantage.	Yes
2. A reliability standard shall neither mandate nor prohibit any specific market structure.	Yes
3. A reliability standard shall not preclude market solutions to achieving compliance with that standard.	Yes
4. A reliability standard shall not require the public disclosure of commercially sensitive information. All market participants shall have equal opportunity to access commercially non-sensitive information that is required for compliance with reliability standards.	Yes

Unofficial Nomination Form

Project 2015-10 Single Points of Failure (TPL-001)

Do not use this form for submitting nominations. Use the electronic form to submit nominations by **8 p.m. Eastern, Friday, August 5, 2016.** This unofficial version is provided to assist nominees in compiling the information necessary to submit the electronic form.

Additional information about this project is available on the Project 2015-10 Single Points of Failure (TPL-001) page. If you have questions, contact NERC Standards Developer, Jordan Mallory (via email), or at (404) 446-9733.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in face-to-face meetings and conference calls. Previous drafting or review team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included below.

Project 2015-10 Single Points of Failure

Modifications have been recommended to Reliability Standard TPL-001-4 based on the following:

Item 1: The System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS) conducted a comprehensive assessment of the study of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.

Item 2: Further, references to MOD-010 and MOD-012 in Requirement R1 would need to be replaced with MOD-032 due to July 2016 retirement of those standards.

In addition, on October 17, 2013 the Commission issued Order No. 786, which included two directives related to TPL-001-4. The two directives are as follows:

- Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six-month threshold could exclude planned maintenance outages of significant facilities from future planning assessments.
- Paragraph 89 directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4."

Standard affected: TPL-001-4

The time commitment for these projects is expected to be up to two face-to-face meetings per quarter (on average two full working days each meeting) with conference calls scheduled as needed to meet the agreed-upon timeline the review or drafting team sets forth. Team members may also have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the drafting team effort is outreach. Members of the team will be expected to conduct industry outreach during the development process to support a successful project outcome.

Please briefly describe your experience and qualifications to serve on the requested Standard Drafting Team (Bio):
If you are currently a member of any NERC drafting team, please list each team here: ☐ Not currently on any active SAR or standard drafting team. ☐ Currently a member of the following team(s):
If you previously worked on any NERC drafting team please identify the team(s): ☐ No prior NERC SAR or standard drafting team. ☐ Prior experience on the following team(s):

Select each NERC Region in which you have experience relevant to the Project for which you are volunteering:		
☐ FRCC	☐ RF	☐ Texas RE
☐ MRO	☐ SERC	☐ WECC
☐ NPCC	☐ SPP RE	☐ NA – Not Applicable

Select each Industry Segment that you represent:	
☐	1 — Transmission Owners
☐	2 — RTOs, ISOs
☐	3 — Load-serving Entities
☐	4 — Transmission-dependent Utilities
☐	5 — Electric Generators
☐	6 — Electricity Brokers, Aggregators, and Marketers
☐	7 — Large Electricity End Users
☐	8 — Small Electricity End Users
☐	9 — Federal, State, and Provincial Regulatory or other Government Entities
☐	10 — Regional Reliability Organizations and Regional Entities
☐	NA – Not Applicable

Select each Function[1] in which you have current or prior expertise:	
☐ Balancing Authority	☐ Transmission Operator
☐ Compliance Enforcement Authority	☐ Transmission Owner
☐ Distribution Provider	☐ Transmission Planner
☐ Generator Operator	☐ Transmission Service Provider
☐ Generator Owner	☐ Purchasing-selling Entity
☐ Interchange Authority	☐ Reliability Coordinator
☐ Load-serving Entity	☐ Reliability Assurer
☐ Market Operator	☐ Resource Planner
☐ Planning Coordinator	

[1] These functions are defined in the NERC Functional Model, which is available on the NERC web site.

Standards Announcement

Project 2015-10 Single Points of Failure
Standard Authorization Request (SAR)

Standard Drafting Team Nomination Period Open through August 5, 2016

Now Available

Nominations are being sought for standard drafting team (SDT) members through **8 p.m. Eastern, Friday, August 5, 2016**.

Use the electronic form to submit a nomination. If you experience any difficulties in using the electronic form, contact Wendy Muller. An unofficial Word version of the nomination form is posted on the Standard Drafting Team Vacancies page and the project page.

By submitting a nomination form, you are indicating your willingness and agreement to actively participate in SDT meetings if appointed by the Standards Committee (SC). If appointed, you are expected to attend most of the face-to-face meetings as well as participate in the meetings held via conference calls.

The time commitment for this project is expected to be up to two face-to-face meetings per quarter (on average three full working days each meeting) with conference calls scheduled as needed to meet the agreed upon timeline the SDT sets forth. Drafting teams may have side projects, either individually or by subgroup, to present to the larger team for discussion and review. Lastly, an important component of the SDT effort is outreach. Members of the team are expected to conduct outreach during development, prior to posting to ensure all issues can be addressed.

Previous drafting team experience is beneficial, but not required. A brief description of the desired qualifications, expected commitment, and other pertinent information is included on the project page and the nomination form.

Next Steps
The SC is expected to appoint members to the team in September 2016. Nominees will be notified shortly after the appointments have been made.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Standards Developer, Jordan Mallory (via email) or at (404) 446-9733.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the first draft of the proposed standard.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	October 29, 2015
SAR posted for comment	May 26 – June 24, 2016

Anticipated Actions	Date
30-day informal comment period with ballot	April 2017
45-day formal comment period with additional ballot	July 2017
45-day formal comment period with additional ballot	October 2017
10-day final ballot	December 2017
Board adoption	February 2018

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None.

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**

2. **Number:** **TPL-001-5**

3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

4. **Applicability:**

   4.1. Functional Entity

   4.1.1. Planning Coordinator.

   4.1.2. Transmission Planner.

5. **Effective Date: See Implementation Plan.**

B. Requirements and Measures

Rationale for Requirement R1:

References to MOD-010 and MOD-012 in Requirement R1 have been replaced with MOD-032, which is now the applicable standard to assemble the network modeling data necessary to meet the TPL-001 requirements. MOD-032-1 superseded MOD-010 and MOD-012, which were retired on 6/30/2016 in the United States.

Rationale for Requirement R1 Part 1.1.2:

In Order 786, Federal Energy Regulatory Commission (FERC) directed NERC to “modify Reliability Standard TPL-001-4 to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments” (P 40). The Commission clarified that its directive is to “include known generator and transmission planned maintenance outages in planning assessments, not hypothetical planned outages” (P 42). FERC stated that NERC had flexibility in addressing the identified concerns and outlined three acceptable approaches, that include:

1. “eliminating the six-month threshold altogether”;
2. “decreasing the threshold to fewer months to include additional significant planned outages”; or
3. “including parameters on what constitutes a significant planned outage based for example on MW or facility ratings.”

See Order No. 786 at P 43.

Order 786 includes the following additional concerns:

- Planned maintenance outages less than six months may result in impacts during peak and off-peak periods (*see* P 41);
- Planned outages during those times should be considered to allow for a single element to be taken out of service without compromising the ability to meet demand (*see* P 41);
- Criticality of elements taken out for maintenance could result in N-1 outage and loss of non-consequential load or impact to reliability (*see* P 41);
- Planned outages are not "hypothetical outages" and should not be treated as multiple contingencies in the planning standard (should be addressed in N-0 base case) (*see* P 42);
- Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages (*see* P 44);
- The Near-Term Transmission Planning Horizon requires annual assessments using Year One or year two, and year five, and known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon (*see* P 45).

The change to Requirement 1 Part 1.1.2 eliminates the specified 6 month outage duration and provides the opportunity for the Reliability Coordinator to assist the Planning Coordinator and/or Transmission Planner to determine which known outages, if any, need to be considered in the Planning Assessment for the Near-Term.

Note: The drafting team points out that this is coordination of known outages beyond the Operations Planning.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities

1.1.2. Known outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

1.1.3. New planned Facilities and changes to existing Facilities

1.1.4. Real and reactive Load forecasts

1.1.5. Known commitments for Firm Transmission Service and Interchange

1.1.6. Resources (supply or demand side) required for Load

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with MOD-032 including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

Rationale for Requirement R2 Part 2.4.5:

In Order No. 786, FERC stated that it believed a stability analysis for spare equipment strategy should exist, similar to the steady state analysis under TPL-001-4 Requirement 2 Part 2.1.5 (*see* P 89). The SDT modified the standard to add R2.4.5, which includes similar language to that used for the steady-state analysis under R2.1.5.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. P1 events in Table 1, as selected in consultation with the Reliability Coordinator, with known outages modeled as specified in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.1.4. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response:

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.4.4. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P1 and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or Special Protection Systems
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5.

3.3. Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.

Rationale for Requirement R4 Part 4.6:

The SPF of a non-redundant Protection System component is a relevant reliability concern for the electrical utility industry and have been identified as the cause of significant system disturbances in past years. (*See Industry Advisory-Protection System Single Point of Failure, Informational Filing of the North American Electric Reliability Corporation in Response to Order No. 754, Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request*). The changes herein clearly establish the TPL-001 standard as requiring corrective actions for Planning Events for which a single point of failure of a non-redundant component of a Protection System, as described by footnote 13. The drafting team took into consideration the recent history of attention given to single point of failure and the tradeoffs with incorporating the 3Ø fault with failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing into the existing P5 or similar, Table 1 event. Consistent with the concerns expressed in FERC Order No. 754, the drafting team decided to maintain the 3Ø fault event in the extreme event section of Table 1, while incorporating a specific Requirement R4 Part 4.6 to develop Corrective Action Plan when analysis concludes that Cascading is caused. By featuring the extreme events 2e-2h listed from the stability column of Table 1 in Requirement 4 Part 4.6, this highlights the single point of failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing as having higher risk than other extreme events, but only demanding corrective action if observed to cause Cascading. This is a reasonable balance of likelihood of the event and its consequences. In this way, the drafting team intends for the extreme events 2e-2h listed from the stability column of Table 1 that cause Cascading to require correction, most likely through Protection System modifications, not simply be evaluated for possible actions designed to reduce the likelihood or mitigate the consequences of the extreme event, in accordance with Requirement R4 Part 4.5.

A planner is permitted to use engineering judgment to select the Protection System component failures for evaluation that would produce the more severe system results or impact, and the evaluation would address all Protection Systems affected by the selected component. A Protection System component failure that impacts one or more Protection Systems and increases the total fault clearing time requires a planner to simulate the full impact (clearing time and facilities removed) on Bulk Electric System performance.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a Special Protection System is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall:

4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

4.3.1.1. Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2. Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3. Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.6. If the analysis concludes there is Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h, a Corrective Action Plan shall be developed. The Corrective Action Plan shall:

4.6.1. List System deficiencies and the associated actions needed to prevent the System from Cascading.

4.6.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:** "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit

   The applicable entity shall keep data identified in Measures M1 through M7 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

   1.3. **Compliance Monitoring and Enforcement Program** As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

   1.4. **Compliance Monitoring Period and Reset Timeframe:** Not applicable.

   1.5. **Compliance Monitoring and Enforcement Processes:**

   - Compliance Audits
   - Self-Certifications
   - Spot Checking
   - Compliance Violation Investigations
   - Self-Reporting
   - Complaints

   1.6. **Additional Compliance Information:** None.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	The responsible entity's System model failed to represent one of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent two of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent three of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, Parts 1.1.1 through 1.1.6. OR The responsible entity's System model did not represent projected System conditions as described in Requirement R1. OR The responsible entity's System model did not use data consistent with that provided in accordance with the MOD-032 standards and other sources, including items represented in the Corrective Action Plan.
R2.	The responsible entity failed to comply with Requirement R2, Part 2.6.	The responsible entity failed to comply with Requirement R2, Part 2.3 or Part 2.8.	The responsible entity failed to comply with one of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, Part 2.5, or Part 2.7.	The responsible entity failed to comply with two or more of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, or Part 2.7. OR The responsible entity does not have a completed annual Planning Assessment.

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R3.	The responsible entity did not identify planning events as described in Requirement R3, Part 3.4 or extreme events as described in Requirement R3, Part 3.5.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for one of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R3, Part 3.2 to assess the impact of extreme events.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for two of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R3, Part 3.3.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for three or more of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies to determine that the BES meets the performance requirements for the P0 or P1 categories in Table 1. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R4.	The responsible entity did not identify planning events as described in Requirement R4, Part 4.4 or extreme events as described in Requirement R4, Part 4.5.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for one of the categories (P1 through P7) in Table 1. OR	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for two of the categories (P1 through P7) in Table 1. OR	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for three or more of the categories (P1 through P7) in Table 1. OR

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
		The responsible entity did not perform studies as specified in Requirement R4, Part 4.2 to assess the impact of extreme events.	The responsible entity did not perform Contingency analysis as described in Requirement R4, Part 4.3. OR The responsible entity did not develop a Corrective Action Plan as described in Requirement R4, Part 4.6.	The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R5.	N/A	N/A	N/A	The responsible entity does not have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, or the transient voltage response for its System.
R6.	N/A	N/A	N/A	The responsible entity failed to define and document the criteria or methodology for System instability used within its analysis as described in Requirement R6.
R7.	N/A	N/A	N/A	The Planning Coordinator, in conjunction with each of its Transmission Planners, failed to determine and identify individual or joint responsibilities for performing required studies.

0	February 8, 2005	BOT Approval	Revised
0	June 3, 2005	Fixed reference in M1 to read TPL-001-0 R2.1 and TPL-001-0 R2.2	Errata
0	July 24, 2007	Corrected reference in M1. to read TPL-001-0 R1 and TPL-001-0 R2.	Errata
0.1	October 29, 2008	BOT adopted errata changes; updated version number to "0.1"	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote 'b' pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC	

Version	Date	Action	Change Tracking
		has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-3 was created after the Board of Trustees approved the revised footnote ‘b’ in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	TBD	Adopted by the NERC Board of Trustees.	Revised To address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. .The process must include the following:

1. Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues
2. Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:
    a. Date, time, and location for the meeting
    b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
    c. Provisions for a stakeholder comment period
3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
    a. System Load level and estimated annual hours of exposure at or above that Load level
    b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency
2. Amount of Non-Consequential Load Loss with:

   a. The estimated number and type of customers affected
   b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community

3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance
4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance
5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12
6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12
7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12
8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

1. The voltage level of the Contingency is greater than 300 kV
   a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or
   b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)
2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW.

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

Rationale for Table 1 P5 Event and Footnote 13:

The revisions to Table 1 Category P5 event require an entity to model a single point of failure of a non-redundant Protection System component that may prevent correct operation of a Protection System, including other Protection Systems impacted by that failed component based on the as-built design of that Protection System. The evaluation shall address all Protection Systems affected by the failed component and the increases (if any) of the total fault clearing time. Footnote 13 provides the attributes of the specific system component failure that the entity shall consider for evaluation.

Changes to the Table 1 P5 event and related footnote 13 are driven by subsequent results of an assessment of Protection System single points of failure in response to FERC Order No. 754. In paragraph 19 of Order No. 754, FERC stated that there is "an issue concerning the study of the non-operation of non-redundant primary Protection Systems; e.g., the study of a single point of failure on Protection Systems." NERC subsequently issued a NERC Section 1600 Request for Data or Information, the results of which were analyzed by the System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS). In their 2015 report "*Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request*," the SPCS and SAMS considered a variety of alternatives to address the reliability risk posed by single points of failure. SPCS and SAMS concluded that the most appropriate recommendation aligning with Order No. 754 directives and maximizing reliability of Protection System performance included modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process.

The SPCS/SAMS report made the recommendations to replace "relay" with "component of a Protection System" in the Table 1 P5 event and replace footnote 13 in TPL-001-4 with alternate wording: "The components from the definition of Protection System for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."

This revision to footnote 13 clarifies the components of the Protection System that must be considered when simulating delayed fault clearing due to the failure of a non-redundant component of a Protection System. The SPCS/SAMS report described voltage or current sensing devices as having a lower level of risk of failure to trip due to robustness and likelihood to actually cause tripping upon failure. Therefore, these components of a Protection System are omitted from footnote 13.

The drafting team sought to limit the scope of protective relays which respond to electrical quantities that may be considered non-redundant components of a Protection System that may experience a single point of failure to those relays that are used for primary protection at the local terminal and applied over the element in question. As typical Protection System designs implement backup protective relaying locally and remotely, the drafting team did not include backup protective relays or overlapping zonal protection as components of a Protection System specified in footnote 13.

Given the increasing importance of communication-aided Protection Systems (e.g., pilot protection schemes, direct transfer tripping schemes, permissive transfer tripping schemes, etc.), the proper operation of the communication system must be considered when considering potential SPF components of Protection Systems. The drafting team augmented the SAMS/SPCS recommendations to include reference to the subset of communication systems that are part of a communication-aided Protection System, necessary where the performance of that Protection System is required to achieve Transmission System Planning Performance Requirements, enumerated in Table 1 of TPL-001-5. In other words, a communication-aided Protection System that may experience a SPF, causing it to operate improperly or not at all, must be considered as part of non-redundancy. The drafting team concluded that the failure of communication-aided Protection Systems may take many forms; however, by alarming and monitoring these systems, the overall risk of impact to the Bulk Electric System is reduced to an acceptable level. Most new Protection Systems deployed in the industry include communication-aided protection with component and communication failure alarms monitored at centralized Control Centers. This alarm monitoring is similar to the requirement associated with station DC supplies. Therefore, this requirement is more applicable to legacy systems that need communication-aided Protection Systems to meet performance requirements of the TPL-001-5 standard.

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability: 1. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. 2. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. 3. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. 4. Simulate Normal Clearing unless otherwise specified. 5. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only**: 1. Applicable Facility Ratings shall not be exceeded. 2. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. 3. Planning event P0 is applicable to steady state only. 4. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only:** Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed

Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. i. 3Ø internal breaker fault. j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss. 2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria. 3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss. 4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service. 5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. 6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground. 7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point. 8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker. 9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered.
10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing.
11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less.
12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.
13. For purposes of this standard, non-redundant components of a Protection System to consider are as follows: a. A single protective relay b. A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported c. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit d. A single control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the first draft of the proposed standard.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	October 29, 2015
SAR posted for comment	May 26 – June 24, 2016

Anticipated Actions	Date
30-day informal comment period with ballot	April 2017
45-day formal comment period with additional ballot	July 2017
45-day formal comment period with additional ballot	October 2017
10-day final ballot	December 2017
Board adoption	February 2018

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

~~Text~~ None.

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**

2. **Number:** **TPL-001-~~4~~5**

3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

4. **Applicability:**

   4.1. Functional Entity

   4.1.1. Planning Coordinator.

   4.1.2. Transmission Planner.

~~5.~~ **Effective Date:** **See Implementation Plan.** ~~Requirements R1 and R7 as well as the definitions shall become effective on the first day of the first calendar quarter, 12 months after applicable regulatory approval. In those jurisdictions where regulatory approval is not required, Requirements R1 and R7 become effective on the first day of the first calendar quarter, 12 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.~~

~~6. Except as indicated below, Requirements R2 through R6 and Requirement R8 shall become effective on the first day of the first calendar quarter, 24 months after applicable regulatory approval. In those jurisdictions where regulatory approval is not required, all requirements, except as noted below, go into effect on the first day of the first calendar quarter, 24 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.~~

~~7. For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-4, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-4:~~

~~8. P1-2 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)~~

~~9. P1-3 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)~~

~~10. P2-1~~

~~11. P2-2 (above 300 kV)~~

~~12. P2-3 (above 300 kV)~~

~~13. P3-1 through P3-5~~

~~14. P4-1 through P4-5 (above 300 kV)~~

~~15.~~5. ~~P5 (above 300 kV)~~

~~16. **Background:** Text (**DELETE GREEN TEXT PRIOR TO PUBLISHING) This section is to only be used for standards that currently have a background section. Going forward standard drafting teams should avoid using this section.**~~

~~17. **Standard-Only Definition:** Text **(DELETE GREEN TEXT PRIOR TO PUBLISHING) This section is to only be used for standards that currently have standard only definitions. Going forward a standard must provide a justification as to why the standard needs a standard-only definition and cannot be moved to the NERC Glossary of Terms.**~~

B. Requirements and Measures

Rationale for Requirement R1:

References to MOD-010 and MOD-012 in Requirement R1 have been replaced with MOD-032, which is now the applicable standard to assemble the network modeling data necessary to meet the TPL-001 requirements. MOD-032-1 superseded MOD-010 and MOD-012, which were retired on 6/30/2016 in the United States.

Rationale for Requirement R1 Part 1.1.2:

In Order 786, Federal Energy Regulatory Commission (FERC) directed NERC to "modify Reliability Standard TPL-001-4 to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments" (P 40). The Commission clarified that its directive is to "include known generator and transmission planned maintenance outages in planning assessments, not hypothetical planned outages" (P 42). FERC stated that NERC had flexibility in addressing the identified concerns and outlined three acceptable approaches, that include:

1. "eliminating the six-month threshold altogether";
2. "decreasing the threshold to fewer months to include additional significant planned outages"; or
3. "including parameters on what constitutes a significant planned outage based for example on MW or facility ratings."

See Order No. 786 at P 43.

Order 786 includes the following additional concerns:

- Planned maintenance outages less than six months may result in impacts during peak and off-peak periods (*see* P 41);
- Planned outages during those times should be considered to allow for a single element to be taken out of service without compromising the ability to meet demand (*see* P 41);
- Criticality of elements taken out for maintenance could result in N-1 outage and loss of non-consequential load or impact to reliability (*see* P 41);
- Planned outages are not "hypothetical outages" and should not be treated as multiple contingencies in the planning standard (should be addressed in N-0 base case) (*see* P 42);
- Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages (*see* P 44);
- The Near-Term Transmission Planning Horizon requires annual assessments using Year One or year two, and year five, and known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon (*see* P 45).

The change to Requirement 1 Part 1.1.2 eliminates the specified 6 month outage duration and provides the opportunity for the Reliability Coordinator to assist the Planning Coordinator and/or Transmission Planner to determine which known outages, if any, need to be considered in the Planning Assessment for the Near-Term.

Note: The drafting team points out that this is coordination of known outages beyond the Operations Planning.

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the ~~MOD-010 and MOD-012~~MOD-032 -standard~~s~~, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities

1.1.2. Known outage(s) of generation or Transmission Facility(ies)~~ with a duration of at least six months~~ as selected in consultation with the

Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and ~~R.~~ 2.4.3.

1.1.3. New planned Facilities and changes to existing Facilities

1.1.4. Real and reactive Load forecasts

1.1.5. Known commitments for Firm Transmission Service and Interchange

1.1.6. Resources (supply or demand side) required for Load

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with ~~MOD-010 and MOD-012,~~ MOD-032 including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

Rationale for Requirement R2 Part 2.4.5:

In Order No. 786, FERC stated that it believed a stability analysis for spare equipment strategy should exist, similar to the steady state analysis under TPL-001-4 Requirement 2 Part 2.1.5 (*see* P 89). The SDT modified the standard to add R2.4.5, which includes similar language to that used for the steady-state analysis under R2.1.5.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. P1 events in Table 1, as selected in consultation with the ~~as directed~~ Reliability Coordinator, with ~~the~~ known outages modeled as specified in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.1.4. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response :

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

~~2.4.3.~~2.4.4. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be studied. The studies shall be performed for the P1 and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or Special Protection Systems
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the

Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5.

3.3. Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.

Rationale for Requirement R4 Part 4.6:

The SPF of a non-redundant Protection System component is a relevant reliability concern for the electrical utility industry and have been identified as the cause of significant system disturbances in past years. (*See Industry Advisory-Protection System Single Point* *of Failure, Informational Filing of the North American Electric Reliability Corporation in Response to Order No. 754, Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request*). The changes herein clearly establish the TPL-001 standard as requiring corrective actions for Planning Events for which a single point of failure of a non-redundant component of a Protection System, as described by footnote 13. The drafting team took into consideration the recent history of attention given to single point of failure and the tradeoffs with incorporating the 3Ø fault with failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing into the existing P5 or similar, Table 1 event. Consistent with the concerns expressed in FERC Order No. 754, the drafting team decided to maintain the 3Ø fault event in the extreme event section of Table 1, while incorporating a specific Requirement R4 Part 4.6 to develop Corrective Action Plan when analysis concludes that Cascading is caused. By featuring the extreme events 2e-2h listed from the stability column of Table 1 in Requirement 4 Part 4.6, this highlights the single point of failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing as having higher risk than other extreme events, but only demanding corrective action if observed to cause Cascading. This is a reasonable balance of likelihood of the event and its consequences. In this way, the drafting team intends for the extreme events 2e-2h listed from the stability column of Table 1 that cause Cascading to require correction, most likely through Protection System modifications, not simply be evaluated for possible actions designed to reduce the likelihood or mitigate the consequences of the extreme event, in accordance with Requirement R4 Part 4.5.

A planner is permitted to use engineering judgment to select the Protection System component failures for evaluation that would produce the more severe system results or impact, and the evaluation would address all Protection Systems affected by the selected component. A Protection System component failure that impacts one or more Protection Systems and increases the total fault clearing time requires a planner to simulate the full impact (clearing time and facilities removed) on Bulk Electric System performance.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a Special Protection System is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall :

4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

4.3.1.1. Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2. Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3. Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.6. If the analysis concludes there is Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h, a Corrective Action Plan shall be developed. The Corrective Action Plan shall:

4.6.1. List ~~s~~System deficiencies and the associated actions needed to prevent the ~~s~~System from Cascading.

4.6.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as

Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and ~~-~~Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

C. Compliance

1. **Compliance Monitoring Process**

~~17.1.~~1.1. **Compliance Enforcement Authority:**

~~**Compliance Enforcement Authority:**~~

"Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

~~17.2.~~1.2. **Evidence Retention:**

The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit.

The applicable entity shall keep data identified in Measures M1 through M7 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

~~17.3.~~1.3. **Compliance Monitoring and Enforcement Program**

As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

~~17.4.~~

~~17.5.~~

~~17.6.~~1.4. ~~1.2~~ **Compliance Monitoring Period and Reset Timeframe:**

Not applicable.

~~17.7.~~

~~17.8.~~1.5. **Compliance Monitoring and Enforcement Processes:**

Compliance Audits

Self-Certifications

Spot Checking

Compliance Violation Investigations

Self-Reporting

Complaints

~~**17.9.Data Retention:**~~

~~The Transmission Planner and Planning Coordinator shall each retain data or evidence to show compliance as identified unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:~~

- ~~The models utilized in the current in-force Planning Assessment and one previous Planning Assessment in accordance with Requirement R1 and Measure M1.~~
- ~~The Planning Assessments performed since the last compliance audit in accordance with Requirement R2 and Measure M2.~~
- ~~The studies performed in support of its Planning Assessments since the last compliance audit in accordance with Requirement R3 and Measure M3.~~
- ~~The studies performed in support of its Planning Assessments since the last compliance audit in accordance with Requirement R4 and Measure M4.~~
- ~~The documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and transient voltage response since the last compliance audit in accordance with Requirement R5 and Measure M5.~~
- ~~The documentation specifying the criteria or methodology utilized in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding in support of its Planning Assessments since the last compliance audit in accordance with Requirement R6 and Measure M6.~~
- ~~The current, in force documentation for the agreement(s) on roles and responsibilities, as well as documentation for the agreements in force since the last compliance audit, in accordance with Requirement R7 and Measure M7.~~

~~The Planning Coordinator shall retain data or evidence to show compliance as identified unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation:~~

- ~~Three calendar years of the notifications employed in accordance with Requirement R8 and Measure M8.~~
- ~~If a Transmission Planner or Planning Coordinator is found non-compliant, it shall keep information related to the non-compliance until found compliant or the time periods specified above, whichever is longer.~~

~~17.10.~~1.6. Additional Compliance Information:

None

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R1.	The responsible entity's System model failed to represent one of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent two of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent three of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, Parts 1.1.1 through 1.1.6. OR The responsible entity's System model did not represent projected System conditions as described in Requirement R1. OR The responsible entity's System model did not use data consistent with that provided in accordance with the ~~MOD-010 and MOD-012~~ MOD-032 standards and other sources, including items represented in the Corrective Action Plan.

R2.	The responsible entity failed to comply with Requirement R2, Part 2.6.	The responsible entity failed to comply with Requirement R2, Part 2.3 or Part 2.8.	The responsible entity failed to comply with one of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, Part 2.5, or Part 2.7.	The responsible entity failed to comply with two or more of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, or Part 2.7. OR The responsible entity does not have a completed annual Planning Assessment.
R3.	The responsible entity did not identify planning events as described in Requirement R3, Part 3.4 or extreme events as described in Requirement R3, Part 3.5.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for one of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R3, Part 3.2 to assess the impact of extreme events.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for two of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R3, Part 3.3.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for three or more of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies to determine that the BES meets the performance requirements for the P0 or P1 categories in Table 1. OR The responsible entity did not base its studies on

				computer simulation models using data provided in Requirement R1.
R4.	The responsible entity did not identify planning events as described in Requirement R4, Part 4.4 or extreme events as described in Requirement R4, Part 4.5.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for one of the categories (P1 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R4, Part 4.2 ~~-~~to assess the impact of extreme events.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for two of the categories (P1 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R4, Part 4.3. OR The responsible entity did not develop a Corrective Action Plan as described in Requirement R4, Part 4.6.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for three or more of the categories (P1 through P7) in Table 1. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R5.	N/A	N/A	N/A	The responsible entity does not have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, or the transient

				voltage response for its System.
R6.	N/A	N/A	N/A	The responsible entity failed to define and document the criteria or methodology for System instability used within its analysis as described in Requirement R6.
R7.	N/A	N/A	N/A	The Planning Coordinator, in conjunction with each of its Transmission Planners, failed to determine and identify individual or joint responsibilities for performing required studies.

Rationale for Table 1 P5 Event and Footnote 13:

The revisions to Table 1 Category P5 event require an entity to model a single point of failure of a non-redundant Protection System component that may prevent correct operation of a Protection System, including other Protection Systems impacted by that failed component based on the as-built design of that Protection System. The evaluation shall address all Protection Systems affected by the failed component and the increases (if any) of the total fault clearing time. Footnote 13 provides the attributes of the specific system component failure that the entity shall consider for evaluation.

Changes to the Table 1 P5 event and related footnote 13 are driven by subsequent results of an assessment of Protection System single points of failure in response to FERC Order No. 754. In paragraph 19 of Order No. 754, FERC stated that there is "an issue concerning the study of the non-operation of non-redundant primary Protection Systems; e.g., the study of a single point of failure on Protection Systems." NERC subsequently issued a NERC Section 1600 Request for Data or Information, the results of which were analyzed by the System Protection and Control Subcommittee (SPCS) and the System Modeling and Analysis Subcommittee (SAMS). In their 2015 report "*Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request*," the SPCS and SAMS considered a variety of alternatives to address the reliability risk posed by single points of failure. SPCS and SAMS concluded that the most appropriate recommendation aligning with Order No. 754 directives and maximizing reliability of Protection System performance included modifying NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process.

The SPCS/SAMS report made the recommendations to replace "relay" with "component of a Protection System" in the Table 1 P5 event and replace footnote 13 in TPL-001-4 with alternate wording: "The components from the definition of Protection System for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."

This revision to footnote 13 clarifies the components of the Protection System that must be considered when simulating delayed fault clearing due to the failure of a non-redundant component of a Protection System. The SPCS/SAMS report described voltage or current sensing devices as having a lower level of risk of failure to trip due to robustness and likelihood to actually cause tripping upon failure. Therefore, these components of a Protection System are omitted from footnote 13.

The drafting team sought to limit the scope of protective relays which respond to electrical quantities that may be considered non-redundant components of a Protection System that may experience a single point of failure to those relays that are used for primary protection at the local terminal and applied over the element in question. As typical Protection System designs implement backup protective relaying locally and remotely, the drafting team did not include backup protective relays or overlapping zonal protection as components of a Protection System specified in footnote 13.

Given the increasing importance of communication-aided Protection Systems (e.g., pilot protection schemes, direct transfer tripping schemes, permissive transfer tripping schemes, etc.), the proper operation of the communication system must be considered when considering potential SPF components of Protection Systems. The drafting team augmented the SAMS/SPCS recommendations to include reference to the subset of communication systems that are part of a communication-aided Protection System, necessary where the performance of that Protection System is required to achieve Transmission System Planning Performance Requirements, enumerated in Table 1 of TPL-

001-5. In other words, a communication-aided Protection System that may experience a SPF, causing it to operate improperly or not at all, must be considered as part of non-redundancy. The drafting team concluded that the failure of communication-aided Protection Systems may take many forms; however, by alarming and monitoring these systems, the overall risk of impact to the Bulk Electric System is reduced to an acceptable level. Most new Protection Systems deployed in the industry include communication-aided protection with component and communication failure alarms monitored at centralized Control Centers. This alarm monitoring is similar to the requirement associated with station DC supplies. Therefore, this requirement is more applicable to legacy systems that need communication-aided Protection Systems to meet performance requirements of the TPL-001-5 standard.

Table 1 – Steady State & Stability Performance Planning Events

Steady State & Stability:

a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur.

b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0.

c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event.

d. Simulate Normal Clearing unless otherwise specified.

e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings.

Steady State Only:

f. Applicable Facility Ratings shall not be exceeded.

g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner.

h. Planning event P0 is applicable to steady state only.

i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements.
Stability Only:
j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P0 No Contingency	Normal System	None	N/A	EHV, HV	No	No
P1 Single Contingency	Normal System	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single Pole of a DC line	SLG			
P2 Single Contingency	Normal System	1. Opening of a line section w/o a fault [7]	N/A	EHV, HV	No[9]	No[12]
		2. Bus Section Fault	SLG	EHV	No[9]	No
				HV	Yes	Yes
		3. Internal Breaker Fault [8] (non-Bus-tie Breaker)	SLG	EHV	No[9]	No
				HV	Yes	Yes
		4. Internal Breaker Fault (Bus-tie Breaker) [8]	SLG	EHV, HV	Yes	Yes

P7 Multiple Contingency *(Common Structure)*	Normal System	The loss of: 1. Any two adjacent (vertically or horizontally) circuits on common structure [11] 2. Loss of a bipolar DC line	SLG	EHV, HV	Yes	Yes

Table 1 – Steady State & Stability Performance Extreme Events

Steady State & Stability

For all extreme events evaluated:

a. Simulate the removal of all elements that Protection Systems and automatic controls are expected to disconnect for each Contingency.

b. Simulate Normal Clearing unless otherwise specified.

Steady State

1. Loss of a single generator, Transmission Circuit, single pole of a DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, single pole of a different DC Line, shunt device, or transformer forced out of service prior to System adjustments.
2. Local area events affecting the Transmission System such as:
    a. Loss of a tower line with three or more circuits.[11]
    b. Loss of all Transmission lines on a common Right-of-Way[11].
    c. Loss of a switching station or substation (loss of one voltage level plus transformers).
    d. Loss of all generating units at a generating station.
    e. Loss of a large Load or major Load center.
3. Wide area events affecting the Transmission System based on System topology such as:
    a. Loss of two generating stations resulting from conditions such as:
        i. Loss of a large gas pipeline into a region or multiple regions that have significant gas-fired generation.

Stability

1. With an initial condition of a single generator, Transmission circuit, single pole of a DC line, shunt device, or transformer forced out of service, apply a 3Ø fault on another single generator, Transmission circuit, single pole of a different DC line, shunt device, or transformer prior to System adjustments.
2. Local or wide area events affecting the Transmission System such as:
    a. 3Ø fault on generator with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
    b. 3Ø fault on Transmission circuit with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
    c. 3Ø fault on transformer with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
    d. 3Ø fault on bus section with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
    e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
    f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

ii. Loss of the use of a large body of water as the cooling source for generation. iii. Wildfires. iv. Severe weather, e.g., hurricanes, tornadoes, etc. v. A successful cyber attack. vi. Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. ~~d.~~i. 3Ø internal breaker fault. ~~e.~~j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss. 2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria. 3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss. 4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service. 5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. 6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground. 7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point. 8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker. 9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered.

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)

10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing.
11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less.
12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.
13. For purposes of this standard, non-redundant components of a Protection System to consider are as follows:
    1. A single protective relay
    2. A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported
    3. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit
    4. A single control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices

    ~~Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).~~

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. .The process must include the following:

1. Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues
2. Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:
    a. Date, time, and location for the meeting
    b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
    c. Provisions for a stakeholder comment period
3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
    a. System Load level and estimated annual hours of exposure at or above that Load level
    b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency
2. Amount of Non-Consequential Load Loss with:

   a. The estimated number and type of customers affected
   b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community
3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance
4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance
5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12
6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12
7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12
8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

1. The voltage level of the Contingency is greater than 300 kV
   a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or
   b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)
2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
0	February 8, 2005	BOT Approval	Revised
0	June 3, 2005	Fixed reference in M1 to read TPL-001-0 R2.1 and TPL-001-0 R2.2	Errata
0	July 24, 2007	Corrected reference in M1. to read TPL-001-0 R1 and TPL-001-0 R2.	Errata
0.1	October 29, 2008	BOT adopted errata changes; updated version number to “0.1”	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote ‘b’ pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees.	

Version	Date	Action	Change Tracking
		TPL-001-3 was created after the Board of Trustees approved the revised footnote 'b' in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	TBD	Adopted by the NERC Board of Trustees.	Revised To address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

Implementation Plan

Project 2015-10 Single Points of Failure
Reliability Standard TPL-001-5

Applicable Standard(s)

- TPL-001-5 – Transmission System Planning Performance Requirements

Requested Retirement(s)

- TPL-001-4 – Transmission System Planning Performance Requirements

Prerequisite Standard(s)

- None

Applicable Entities

- Planning Coordinator
- Transmission Planner

Background

Reliability Standard TPL-001-5 revises the prior version of the TPL-001 standard in three key respects:

- To address reliability issues concerning the study of single points of failure on Protection Systems, as identified in Federal Energy Regulatory Commission (FERC) Order No. 754 issued September 15, 2011 and the NERC Planning Committee System Protection and Control Subcommittee and System Analysis and Modeling Subcommittee September 2015 report titled *Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request;*
- To address directives from FERC Order No. 786 issued October 17, 2013, in which FERC approved Reliability Standard TPL-001-4; and
- To replace references to the MOD-010 and MOD-012 standards, which have been superseded by the MOD-032 Reliability Standard.

General Considerations

The 36-month implementation period for TPL-001-5 provides Planning Coordinators and Transmission Planners with time to update their annual Planning Assessments to include the new System models and studies required by the standard. This implementation period reflects consideration that Planning Coordinators and Transmission Planners will need time to develop, among other things:

- A process for coordinating with the Reliability Coordinator which known outages of generation of Transmission Facilities of less than six months shall be represented in planning studies;
- A process for establishing coordination with protection engineers to obtain the necessary data to perform the single points of failure analysis required by the standard; and
- Additional base case models and analysis.

In addition, the implementation plan includes an additional 24 month period for the development of Corrective Action Plans under TPL-001-5 to address newly-added studies involving single points of failure on Protection Systems. This implementation period reflects consideration that Planning Coordinators and Transmission Planners will need time beyond that provided to conduct the new studies and analysis to develop processes for coordination with asset owners and protection engineers to identify appropriate Corrective Action Plan actions and establish the associated timetables for completion. This includes:

- Any necessary Corrective Action Plans to address Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h required by TPL-001-5 Requirement R4 Part 4.6; and
- Any necessary Corrective Action Plans to address System performance issues for studies involving Table 1 Category P5 Multiple Contingency (Fault plus non-redundant component of a Protection System failure to operate) required by TPL-001-5 Requirement R2 Part 2.7 for the following non-redundant components of a Protection System identified in TPL-001-5 Table 1 Footnote 13, items 2-4:
  - A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported
  - A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit
  - A single control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Lastly, the provisions related to Corrective Action Plans including Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3) are carried forward from the TPL-001-4 implementation plan.

Effective Date

TPL-001-5 – Transmission System Planning Performance Requirements

Where approval by an applicable governmental authority is required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Compliance Date for TPL-001-5 Requirement R4, Part 4.6 and Requirement 2, Part 2.7 associated with Table 1 Category P5 Footnote 13 items 2, 3, and 4

Entities shall not be required to comply with Requirement R4, Part 4.6 until 24 months after the effective date of Reliability Standard TPL-001-5.

Entitles shall not be required to comply with Requirement R2, Part 2.7 for the Table 1 Category P5 planning event for the non-redundant components of a Protection System identified in footnote 13 items 2, 3, and 4 until 24 months after the effective date of Reliability Standard TPL-001-5.

Note Regarding Corrective Action Plans

For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval of TPL-001-4, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-5, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-5:

- P1-2 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)
- P1-3 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)
- P2-1
- P2-2 (above 300 kV)
- P2-3 (above 300 kV)
- P3-1 through P3-5
- P4-1 through P4-5 (above 300 kV)
- P5 (above 300 kV)

Initial Performance of Periodic Requirements

Each responsible entity shall complete the first annual Planning Assessment in accordance with TPL-001-5 by the effective date of the standard.

Each responsible entity shall complete any required Corrective Action Plans under Requirement R4, Part 4.6 and Requirement R2, Part 2.7 associated with the non-redundant components of a

Protection System identified in Table 1 Category P5 Footnote 13 items 2, 3, and 4 by 24 months after the effective date of Reliability Standard TPL-001-5.

Retirement Date

TPL-001-4 – Transmission System Planning Performance Requirements

Reliability Standard TPL-001-4 shall be retired immediately prior to the effective date of TPL-001-5 in the particular jurisdiction in which the revised standard is becoming effective.

Unofficial Comment Form

Project 2015-10 Single Points of Failure
TPL-001-5

Do not use this form for submitting comments. Use the electronic form to submit comments on **TPL-001-5 – Transmission System Planning Performance Requirements**. The electronic form must be submitted by **8 p.m. Eastern, Wednesday, May 24, 2017.**

Additional information is available on the project page. If you have questions, contact Standards Developer, Latrice Harkness (via email), or at (404) 446-9728.

Background Information

The SPCS and the SAMS conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action**.**

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Questions

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

   ☐ Yes
   ☐ No

   Comments:

2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?

   ☐ Yes
   ☐ No

   Comments:

3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?

   ☐ Yes
   ☐ No

   Comments:

4. Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?

   ☐ Yes
   ☐ No

   Comments:

5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))

   ☐ Yes
   ☐ No

   Comments:

6. Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?

   ☐ Yes
   ☐ No

   Comments:

7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

   ☐ Yes
   ☐ No

   Comments:

8. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

   ☐ Yes
   ☐ No

   Comments:

9. Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?

   ☐ Yes
   ☐ No

   Comments:

10. Do you have any other general recommendations/considerations for the drafting team?

   ☐ Yes

Standards Announcement

Project 2015-10 Single Points of Failure
TPL-001-5

Informal Comment Period Open through May 24, 2017

Now Available

A 30-day informal comment period for **TPL-001-5 – Transmission System Planning Performance Requirements**, is open through **8 p.m. Eastern, Wednesday, May 24, 2017**.

Commenting

Use the electronic form to submit comments on the standard. If you experience any difficulties in using the electronic form, contact Wendy Muller. An unofficial Word version of the comment form is posted on the project page.

If you are having difficulty accessing the Standards Balloting & Commenting System (SBS) due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).

- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

The drafting team will consider all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual**.**

For more information or assistance, contact Senior Standards Developer, Latrice Harkness (via email) or at (404) 446-9728.

North American Electric Reliability Corporation

Comment Report

Project Name:	2015-10 Single Points of Failure | TPL-001-5
Comment Period Start Date:	4/25/2017
Comment Period End Date:	5/24/2017
Associated Ballots:	

There were 63 sets of responses, including comments from approximately 180 different people from approximately 129 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?

3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?

4. Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?

5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))

6. Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?

7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

8. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

9. Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?

10. Do you have any other general recommendations / considerations for the drafting team?

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

Leonard Kula - Independent Electricity System Operator - 2

Answer	No

Document Name	
Comment	

There are a few concerns that are introduced by the proposed modification of part 1.1.2:

- Order 786 specifically mentions that TPL-001 is intended to analyze the Near-Term Transmission Planning Horizon and requires annual assessments using Year One or year two, and year five. However, outages planned to occur within the next 12-months should be analyzed per the Operations Planning requirements of IRO-017 which is intended to cover the Operations Planning time horizon. Therefore, only outages planned for this timeframe (more than 12-months forward) in advance are appropriate to be required to be analyzed as a requirement of a Transmission Planning standard such as TPL-001 and the standard should not involve the RC.

- Moving from a firm threshold to consultation creates ambiguity and potential reliability gaps, and is not an effective means to address the FERC concerns expressed in Order 786. when there are no criteria as to how that consultation is to proceed.

- Replacing the 6-month threshold with a consultation with the RC has the following potential shortfalls:

    1. The TP's/PC's footprint is not necessarily the same as the RC's; there can be several RCs within a TP/PC area, or the other way around. In these cases, who should be consulted and how to reach an agreement if multiple entities are involved? And on what basis should the RC(s) recommend inclusion of certain planned outages?

    2. While the draft standard places an obligation on the TP/PC to consult, there is no mirror obligation on the RC to respond. What if the RC does not respond? Is the TP/PC held non-compliant for having no planned outages included in the planning assessment?

    3. Two entities may be assessing the same system conditions included the planned outages, but they could come up with quite different assessment results due to different risk tolerances or approaches applied in the assessment. If the TP/PC and the RC, or multiple RCs when more than one is involved, come up with different assessment results, whose results should prevail?

To address the FERC directive without the above potential reliability gaps or shortfalls, we offer the following suggestions:

1. Conduct sensitivity testing to identify those planned outages with a duration of more than 1 month but less than 6 months that can have a reliability impact in the planning horizon, and

2. Reflect them in the base model along with those planned outages with a duration of 6 months or longer.

The above can be achieved by revising Part 1.1.2, returning Part 2.1.3 to the existing wording and adding a bullet under Part 2.1.4, as follows:

Part 1.1.2: Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months, and those planned outages identified through sensitivity testing in Part 2.1.4 as having a reliability impact in the planning assessment horizon. Part 2.1.3: P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled. Part 2.1.4: Adding the bullet at the end of the list: • Planned outages of generation or transmission Facility(ies) with a duration of more than 1 month but less than 6 months.

Comment	

We do not agree with the concept of removing the 6 month duration outage and we have concerns with the idea of consultation with the Reliability Coordinator (RC). We also disagree with the contention that N-1-1 analyses as specified by P3 and P6 events are not sufficient to address the near term planning horizon reliability concern.

The 6 month known outage duration in the existing standard version, while possibly arbitrary to reliability, does provide some level of objectivity when identifying outages. In contrast, the proposed language is too subjective and open to interpretation. The idea of consulting with the RC to identify known outages, while possibly relevant, adds to the lack of objectivity in identifying known outages and increases the level of complexity in identifying known outages. This idea also does not provide clear ownership for the identification of known outages. In summary, we feel the 6 month known outage duration in the existing standard version balances objectivity and complexity.

As an alternative, we would suggest the SDT investigate the possibility of taking a step back and altering this specific requirement to make it applicable to the TOP and also the TP. The TOP may be in the best position to be aware of known / planned outages in the near term planning horizon, and to be able to identify such outages to the TP. As stated in the rationale, the goal is not to consider hypothetical outages. The TOP may be in the best position to identify known / planned outages, prioritize them in terms of reliability impact, and then them provide to the TP for analysis in the annual near term planning horizon planning assessment.

Regarding the stated contention that N-1-1 analyses as specified by P3 and P6 events are not sufficient to address the near term planning horizon reliability concern, we would disagree. In practice, P3 and P6 should be sufficient as a proxy to assess the impact of an outage followed by another P1 event, as required by Req #2.1.3. The intent of R2.1.3 is to model an outage as an N-0 condition, and then apply and assess a P1 event.

For this same reason, we do not agree with the new proposed Req #2.4.3 (stability analysis considering known outages). In practice, this modified requirement is somewhat redundant with Table 1, P3 and P6 events. P3 and P6 events are applicable for stability analysis. The additional study burden (or compliance burden) may not be commensurate with the expected incremental reliability benefit. If this requirement will be maintained, then the wording should be consistent with the modified requirement 2.1.3.

Finally, It appears there may be a wording error in the modified Req #2.1.3. Req # 2.1.3 should be modified / clarified to state that “P1 events in Table 1, as selected in consultation with the as directed Reliability Coordinator, with the known outages modeled as specified in Requirement R1, Part 1.1.2 (outages selected in consultation with the Reliability Coordinator) under those System peak or Off-Peak conditions when known outages are scheduled.” Our understanding is that the objective is to have the RC consult in the selection of known outages, and not necessarily in the selection of P1 events.

Comment

The new requirement does not address a scenario where the TP does not agree with the RC regarding what needs to be studied, or how such a disagreement would be managed from the compliance perspective. The “limited known outages” statement in Question 1 is not part of R1.

We recommend the Requirements 1.1.2 and 2.1.3 be revised as follows to clarify which entity has the sole responsibility to select the outages (additions in **BOLD**):

R1.1.2 Known outage(s) of generation or Transmission Facility(ies) as selected **by the Transmission Planner following** consultation with the Reliability Coordinator for the Near-Term **Transmission** Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3. R2.1.3. P1 events in Table 1, as selected **by the Transmission Planner following** consultation with the Reliability Coordinator, with known outages modeled as specified in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled. Alternatively RC should be removed from these Requirements and TP should have the flexibility to select what needs to be studied; as it relates to outages. In addition, this new requirement would result in Transmission Planners (TP) performing an annual study as the RC could request a study to review upcoming outages. This could result in a conflict with the existing Requirements that allow the use of past studies to satisfy compliance with TPL-001.

Comment	
We are comfortable with the move away from the 6 month minimum duration outage requirement. However, we feel strongly that the outages selected by the PC/TP in consultation with their RC should be limited to known outages for the time period beyond 12-months from the current date to year 5. Since the proposed revision uses the term 'Near-Term Planning Horizon' this would inadvertently include the first year which is an Operational Planning responsibility. The TPL-001 standard is intended for Transmission Planning, not Operations Planning, and is focused on analyzing the transmission system for necessary upgrades to maintain reliability. These upgrades require well over 12-months to plan, design, permit, and construct. Required analysis of outages planned in the timeframe of less than 1 year from the current date should be the exclusive responsibility of Operations Planning through reliability standards such as IRO-017 which are intended to cover the Operations Planning time horizon

SDG&E reads the sentence, "in consultation with the Reliability Coordinator", to mean that the Transmission Planner and Planning Coordinator would be required to have the list of maintenance outages assessed approved by its Reliability Coordinator [PeakRC]. This would shift some of the responsibility for TPL-001 from the TP/PC to the RC and it is unlikely that an RC would approve a list of know outages which did not include all know outages (a subset of the complete list) without first assessing each outage on the list. Requiring the RC to approve ***all*** *known outages within its territory will place an unreasonable burden on the RC and the TPs/PCs. SDG&E recommends removing the language, "in consultation with the Reliability Coordinator" from 1.1.2 and 2.1.3.* *SDG&E agrees with the addition of section 2.4.3. The original language in requirement R1.3.12 read, "Include the planned (including maintenance) outage of any bulk electric equipment (including protection systems or their components) at those demand levels for which planned (including maintenance) outages are performed." This language is reflected in 2.4.3 and serves to limit the study of known – planned - outages to those periods when maintenance is typically done (Off-peak load periods). It also captures known outages of long duration which may not be completed before the next peak load period occurs (System peak load).*

Comment	

While AEP does not object outright to the proposed change that the outages be determined as a result of consultation between the PC/TP and RC, we wonder if such an approach might perhaps lead to inconsistent application and methodologies across the system? The Standards Drafting Team may wish to consider this possibility themselves, and weigh the likelihood of such inconsistencies. The text "as selected in consultation with the Reliability Coordinator" has been inserted at the wrong location within R.2.1.3. As currently proposed, it appears that it the P1 events, rather than the outages themselves, which are being selected in consultation with the Reliability Coordinator.

BPA agrees with moving away from the 6-month fixed duration outages. BPA does not agree that consultation with the Reliability Coordinator is necessary. BPA believes the extra coordination would be burdensome and would not provide additional value. BPA already participates in a 45 day regional outage coordination process. BPA believes that this regional coordination process is sufficient to identify the outages to meet Requirement 1, Part 1.1.2.

Comment	
TVA does not agree with the change to Requirement 1, Part 1.1.2. The Planning Coordinator and Transmission Planners have the capability and understanding to select outages that should be included in their Near-term Planning horizion. For those Reliability Coordinators with a significant number of Transmission Planners and Planning Coordinators in their footprint, this requirement change would add a significant burden on the Reliabiltiy Coordinators without benefit to the process. The focus of the Reliabililty Coordinator is in the real-time to one year horizon, Transmisison Planning should be focused on the one year to five year horizon. If there needs to be an entity to oversee and advise the TPL studies conducted by the Transmission Planner it should be the role of the Planning Coordinator. In addition, these studies are already being performed in the operational arena, therefore there is no benefit in recreating this analysis in the planning horizon. Even if problems were found in the planning horizon, the corrective action(s) would be to forego the outage or to create an op guide. The operational cases have a more accurate near term load/generation profile which are more appropriate for these studies. Recreating these studies in the planning horizon would add no value, but take significant new effort and time to complete.

John Babik - JEA - 1,3,5	
Answer	No
Document Name	
Comment	
JEA appreciates the effort of the SDT addressing the directives from the Commission on Order No. 786 issued on Oct. 17, 2013, Paragraph 40. This standard is applicable only to PCs and TPs per the Applicability section, thus RCs are not under any compliance burden. So what course of actions can the PCs and TPs take to show compliance if they do not receive due cooperation/consultation from the RCs? Please see the comment under #5 below as well. The changes add extra burden on the PCs and TPs for compliance on which they have no control. Additionally, the outage coordination seems to be more of an Operational Planning issue (for next-day studies up to six months) than a Transmission Planning issue (one to ten years studies). No matter how far ahead PCs and TPs study the system, when it comes to the Operation horizon, the outages	

need to be studied again with a more realistic system conditions than in the Planning Horizon. Hence any specific analyses performed by PCs and TPs for the outages in the Planning Horizon don't provide much value to the system operators in the Operation horizon.

Besides, if the system can't meet the performance requirements due to outages as per R2.1.3 and R2.4.3, the TPs and PCs have no other allowed mitigation plans, such as operational procedures, except to recommend Corrective Action Plans which result in capital improvement projects. Thus planning for outages in the Near-term Transmission Planning Horizon will only result in capital investment that effect the rates of our customers unnecessarily.

Instead standard **IRO-017 – Outage Coordination** seems to be a much better place to have this directive from Paragraph 40 of Order No. 786 addressed.

Suggestion: Keep the existing language of R1.1.2 unchanged from TPL-001-4 and address this in a future revision of IRO-017

larry brusseau - Corn Belt Power Cooperative - 1	
Answer	No
Document Name	Project 2015-10 TPL-001-5 CBPC.docx
Comment	

Corn Belt agrees with the SPP Standards Review Group and its clarification of an important issue regarding the expectations of regulatory staff on the impacts of Requirement 1, Part 1.1.2. The clarification is about the differences in power flow case topologies used by SPP Operations and SPP Planning. Issues found in the operating horizon would be specific to that point in time and would take into consideration any planned outages, forced outages, generation dispatch, transfers, and load levels that would cause concerns. These operating horizon variables would be changing from minute to hour to day to week to month to season to year. The same outage placed in a planning horizon assessment would be placed into a model that has a lot fewer outages, different generation dispatch, different transfer levels, and different load levels. The topology differences between the two power flow models is significant enough that the operation horizon outages would more than likely not cause issues in the Transmission System Planning Performance Requirements (TPL) Assessment. Further, the SPP Standards Review Group states that trying to mimic, follow, or forecast these operating horizon outages in a meaningful manner would be a moving target. This is due to the fact that most of the planned outages are due to maintenance and capital projects that usually do not re-occur within a 3-5 year period, if ever. The SPP Standards Review Group also found the proposed language to be vague and ambiguous, regarding the timeframe, and therefore would be hard to defend during an audit.

Corn Belt agrees with the SPP Standards Review Group that the language is unclear as to whether outages should be evaluated only in the season for which they are planned or whether they should be evaluated for the peak or off-peak 1 or 2, and 5 planning horizon. In addition, the reference to the number of additional cases and the associated seasons that could be required. Corn Belt agrees with the SPP Standards Review Group suggested proposed language that would tie this process to the TOP Standards instead of the TPL Standards as this is pertaining more to operation related issues.

Also concerned that this could significantly increase the number of near term cases created and studied and add significant work load to tune L&R for these cases. Concern this will significantly increase PC/TP study work load without benefit due to undetermentant amount of outages that need studied. Even though the 6 month duration may not be perfect, it did provide specific criteria to select outages to study. Concern this change will result in significant wasted time and effort to produce results that won't ultimately be used because the same outages will be restudied in ops horizon.

> Outages of concern to be studied separately. Base case assumptions.[A1]
>
> Suggested Language:[A2]
> R1.1.2 Known critical outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

Firmly disagree with the bullet in the Rationale for Requirement R1 Part 1.1.2. "Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages (see P 44);" Category P3 and P6 does sufficiently cover most maintenance outages any utility would expect and the criteria for R1.1.2 should define outages beyond those that are normaly studied as Category P3 and P6.

Futher, the word "limited" in the comment form Question 1 above is not in the proposed language of R1.1.2, and is misleading by implying the intent is for a "small number of" outages. If the intent is for the PC/TP's to study only a limited amount of outages (beyond those already studies as P3 and P6's) then edit the language to state so.

Comment	

Outage studies — for planned or unplanned outages of any duration — are handled now in the operational horizon with RC coordination. The duration of the outage shouldn't matter. This change would create unnecessary additional work.

WAPA agrees with the intent to include significant impactful outages that are important to evaluate ahead of what is covered in the Operations Horizon, but we need to ensure that the language change to Requirement 1, Part 1.1.2 supports this intent. It is essential that the scope of outages be limited to significant planned outages that are not hypothetical in nature. Otherwise, there is a concern that this could significantly increase PC/TP study work without an appreciable benefit due to an undeterminant amount of outages that need to be studied. Outage scheduling changes could occur potentially leading to the results from the R1.1.2 analysis becoming irrelevant as it gets closer to when the outage will actually occur (Operations Horizon). These outages will need to be restudied in the Operations Horizon using more accurate information anyway. Even though the 6 month duration may not be perfect, it did provide specific criteria to select outages to study. There is a risk that the proposed language change to R1.1.2 could lead to it being left wide-open regarding what should be included in a Planning model because there are no parameters on what constitutes a significant planned outage.

WAPA disagrees with the bullet in the Rationale for Requirement R1 Part 1.1.2. "Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages (see P 44);" Category P3 and P6 does sufficiently cover most maintenance outages any utility would expect and the criteria for R1.1.2 should define outages beyond those that are normaly studied as Category P3 and P6.

Futher, the word "limited" in the comment form Question 1 above is not in the proposed language of R1.1.2, and is misleading by implying the intent is for a "small number of" outages. If the intent is for the PC/TP's to study only a limited amount of outages (beyond those already studies as P3 and P6's) then edit the language to state so.

Suggested Language (add a qualifier to specify these outages should be critical/significant in nature and leave the ultimate decision upon what constitutes a significan planned outage to the PC/TP per R1 that, "shall maintain System models… to complete its Planning Assessment"):

Idaho Power disagrees with the concept to move away from the 6 month outage duration. While it is reasonable to include known outages that will occur in the time horizon being studied, it's unclear how the consultation with the RC will work; in general, the RC is rarely aware of outages 1 to 5 years out unless they are long term (lasting more than 6 months).

Comment	

PGE agrees in principal to coordinating with the RC when selecting outages to study as part of the TPL assessment. The removal of the 6 Month duration, however, without new language to define the criticality of planned outages to be studied is not recommended. Planned projects require many outages for completion, some as short as a few days and some much longer. The full list of required outages cannot be known in the planning horizon. Without specific criteria for identifying outages, the RC cannot know the criticality without study, creating a paradox. This proposal could potentially require the creation new case for every identified outage, regardless of outage duration, significantly increasing the work required to complete the TPL analysis. It has been PGE’s experience that a single construction outage rarely results in significant impacts to the BES. When several outages overlap, the BES may be affected. It is not possible to know how outages will overlap in the planning horizon. This risk is managed in the Operations Horizon in the NW via the 45 Day Outage Scheduling Process.

The additional requirement to study planned outages in the dynamics analysis section 2.4.3 will be extremely burdensome and not necessary for similar reasons to those stated above.

AZPS supports retaining the 6 month threshold as anything less than 6 months may only be a temporary system configuration. The TPL Assessment is a planning assessment and should be limited to standard system configurations. The Operating horizon should address anything occurring in less than 6 months. On a case by case basis outages of shorter duration could be included if mutually agreed upon by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs).

Outage schedules are market-sensitive information. Outages planned for later years often are not posted to OASIS due to the volatility of outage scheduling long in advance of the outage. Putting these outages in models which are then shared with other Transmission Planners risks improperly sharing this market sensitive information outside the OASIS process.

While we recognize the importance of coordinating outage information, long-term planning models are generally outside the timeframe of interest to Reliability Coordinators. Without a compliance requirement to be involved in the process, it is likely that RCs will not give this process the attention it needs to be effective. The requirement to consult with the RC should be either removed, or a requirement should be added for RCs to respond to these consultation requests in a timely fashion.

Transmission Planners need the leeway to model outages appropriately. It is possible to have mutually exclusive outages which can be applied to a model based on the peak or off-beak conditions being modeled. For instance, outages may be scheduled for multiple sections of a line as part of a line reconductoring project. While all of these outages may fall in the same off-peak season, only one of them will be in effect at a time. It is also within the RCs authority to cancel planned outages that degrade the reliability of the system. Developing projects for outages that are optional would not be appropriate unless it was determined that the planned outage was both required and not feasible without reliability challenges deemed to significant to allow by the RC. TPs should be explicitly allowed to select outages based on criteria beyond the scheduling of the outage in order to accurately model the effects of the outage plan.

NIPSCO believes any potential issues associated with planned maintenance outages are best identified through operational studies such as real time, next-day, and seasonal analysis rather than through the annual TPL-001-4 system performance analysis. Planned maintenance outages are almost always of short duration and are commonly scheduled to avoid occurrence during critical peak seasons. Only planned maintenance outages which are reasonably expected to occur during critical peak seasons, such as those six months or longer, should be included in the annual TPL-001-4 system performance analysis.

Removing the existing six month threshold for planned maintenance outages and continually reducing the time of duration requires the analysis of an ever greater number of concurrent generator and line outages beyond any specified in the TPL-001-4 standard including (P2) bus+breaker fault, (P4) stuck breaker, and (P7) common tower. This moves the performance analysis requirements of the TPL-001-4 standard closer to an effective N-2 requirement which was never intended.

Answer	No
Document Name	
Comment	
The following answers to all the questions are from our City Light subject matter experts: Comments: The PCs and TPs are responsible for complying to the TPL-001-4 standard. RCs are under no obligation to comply with same and have no reason to have input on planning horizon outages (more than 1 year out) that are outside the operations planning horizon (less than 1 year out). As indicated in response to question 5, it is agreed that no additional entities should be added to the applicability of this standard, including the RC, who is focused on the operations of the system. A gap in communication between PCs/TPs and RCs may put the PCs/TPs in a position where compliance for this standard are not met. In the planning horizon, the PC and TP would be the more appropriate entities to be able to identify significant outages. When planning for outages in the near-term planning horizon, considering outages that are longer than 6 months is appropriate. If the 6 month duration is removed, there are too many planned outages that occur regularly that may be identified to be included in the study even when it is not necessary and would be studied in the outage coordination process. Suggestion: Keep the language in the R1.1.2 of the TPL-001-4 standard.

Comment	

The aspects of the current TPL-001-4 and proposed TPL-001-5 standards that address the area of planned maintenance outages mischaracterize the role of transmission planning – which is to provide for an orderly transmission expansion program that ensures the transmission system is adequate, reliable, and resilient at all times in the future given the lead times associated with making necessary system improvements. Adequacy, reliability, and resiliency include the flexibility of a transmission system to allow for the planned outage of any single transmission facility during non-peak periods in a manner that i) does not require the curtailment of firm load and ii) provides for the system to be operated in an N-1 secure state after the single transmission facility has been removed from service for planned maintenance. All transmission facilities require planned outages from time-to-time to facilitate i) maintenance, testing, and/or repair work that cannot be performed hot; ii) to facilitate protection scheme testing, maintenance, and upgrades on facilities with non-redundant protection; iii) to facilitate capital upgrades to the transmission system or other facilities in the vicinity of the transmission facility; or iv) for other purposes. Therefore, the eventual occurrence of a future planned outage on any transmission facility is certain and “known”, not “hypothetical”, only the timing and duration of the future outage could be considered uncertain or “hypothetical”.   If the transmission system is not planned in a manner that allows for any single facility to be removed for maintenance under non-peak conditions, then the system will not maintain the necessary adequacy and resiliency to accommodate planned maintenance requirements in general.

In FERC Order 786, the Commission indicated the following at PP 41:

“We agree with commenters such as MISO and ATCLLC that certain elements may be so critical that, when taken out of service for system maintenance or to facilitate a new capital project, a subsequent unplanned outage initiated by a single-event could result in the loss of non-consequential load or may have a detrimental impact to the bulk electric system reliability. A properly planned transmission system should ensure the known, planned removal of facilities (i.e., generation, transmission or protection system facilities) for maintenance purposes without the loss of non-consequential load or detrimental impacts to system reliability such as cascading, voltage instability or uncontrolled islanding.” (emphasis added)

It is “known” that every transmission facility will eventually need to be taken out of service for planned maintenance or other purposes, thus the prudent planning approach to planned maintenance outages should be to ensure that the transmission system is planned with sufficient resiliency to accommodate planned maintenance outages during off-peak periods that will be required regardless of whether or not such activity has been scheduled.

Direction on ensuring the system could me TPL criteria for future potential planned outages was previously given in an interpretation to TPL-002 and TPL-003. Please consider this, as its intent appears to be lost in forming the TPL-001-4 standard.

http://www.nerc.com/docs/standards/sar/MISO_Interpretation_TPL_Revised_20Mar08.pdf

http://www.nerc.com/files/TPL-002-2b.pdf Pg 11

"The following interpretation of TPL-002-0 and TPL-003-0 Requirement R1.3.12 was developed by the NERC Planning Committee on March 13, 2008:

This provision was not previously interpreted by NERC since its approval by FERC and other regulatory authorities. TPL-002-0 and TPL-003-0 explicitly provide that the inclusion of planned (including maintenance) outages of any bulk electric equipment at demand levels for which the planned outages are required. For studies that include planned outages, compliance with the contingency assessment for TPL-002-0 and TPL-003-0 as outlined in Table 1 would include any necessary system adjustments which might be required to accommodate planned outages since a planned outage is not a "contingency" as defined in the *NERC Glossary of Terms Used in Standards."*

While some have argued that outages can be fully managed by outage coordination efforts focused on the operating horizon, if the system is not planned and expanded to maintain sufficient adequacy and resiliency to support future outages, the outage coordination functions may be backed into a corner where there is no choice but to shed load to accommodate an outage or deny an outage given the inability of the outage coordination function to make the necessary system upgrades in the operating horizon that should have been made by the planning function within the planning horizon. An important function of planning is to support operations, which includes ensuring the system is adequate and robust enough to provide flexibility to the outage coordination function to schedules planned outages when they are needed without sacrificing reliability or load continuity.

A proposed remedy would be to expand the P3 and P6 contingency definitions to evaluate an additional multiple outage scenario with no load loss. This scenario would include a planned outage, system adjustments, and then a contingency, but no consequential or non-consequential load loss would be allowed for the planned outage element, and no non-consequential load loss would be allowed for the contingent element. This scenario would be evaluated only for non-peak conditions. The idea here is that the system does not need to be planned to support planned maintenance during peak load conditions, since those conditions represent a very small percentage of time. However, under periods where planned maintenance is typically performed (e.g., shoulder peak and light load conditions, etc.), the system should be planned to accommodate the planned outage of any one system element (transmission or generation) while ensuring the system can continue to operate in a manner that is N-1 secure with no non-consequential load loss. This additional aspect of the P3 and P6 contingencies will require an adjustment to the traditional contingency definitions to facilitate service to all loads for the planned maintenance outage element in accordance with how the system would be switched for planned maintenance. For example, the planned maintenance outage of a network transmission line section with tapped distribution substations served by the line would be switch-to-switch (only the section between two adjacent distribution substations that required maintenance would be taken out of service) instead of breaker-to-breaker to ensure all

load could continue to be served during the planned maintenance outage. This change to the standard ensures that there is a minimal level of flexibility to provide for the planned outage of any single element in the system, which better aligns with the overall goal of transmission planning to ensure the system is adequate, resilient, and reliable in the future.

Comment	
Comments: Santee Cooper appreciates the effort of the SDT addressing the directives from the Commission on Order No. 786. This standard is applicable only to Planning Coordinators and Tranmission Planners per the Applicability section and as such the Reliability Coorindators should not be placed under any compliance burden. Adding the Reliability Coordinator adds an extra burden on the PCs and TPs to demonstrate compliance. Order 786 does not require the Reliability Coordinator to be consulted with on outages. The requirement to consult with the Reliability Coordinator should be removed from this standard. Recommend to keep the existing language of R1.1.2 the same as in the current approved version. Outage coordination is studied in the operational planning horizon in accordance with IRO-017 – Outage Coordination. No matter how far ahead PCs and TPs study the system, when it comes to the operational planning horizon, the outages need to be studied again with anticipated system conditions. Any specific analyses performed by PCs and TPs for the outages in the Planning Horizon do not provide much value for Real-time operations.

Darnez Gresham - Berkshire Hathaway - PacifiCorp - 6 - WECC	
Answer	No

Document Name	
Comment	

PacifiCorp agrees that a Transmission Planner in coordination with the Reliability Coordinator should determine which known outages should be studied, but requests the drafting team to provide more clearly defined guidance to both the reliability coordinator and transmission plannner as to the kind of outages that should be considered for this analysis. For example, a known outage of a generator greater than 500 MVA should be studied or a known outage of a transmission element with a facility rating of 800 MVA or higher should be studied. In addition to providing thresholds for outages to be considered, PacifiCorp believes that the drafting team should also consider FERC's option of reducing the duration from 6 months to either 3 or 4 months, otherwise there would be no distinction between momentary outage as simulated per the P3 and P6 event, as compared to a known outage that can change dispatch patterns and expose the system to a reliability issue.

PacifiCorp believes that performing a known outage analysis for year one or year two case provides benefit for both operational and planning horizon, but performing the known outage analysis for a 5 year case does not provide any benefit as the system conditions could have changed significantly and are not known while performing the TPL assessment.

We respectfully disagree with several aspects of this proposal. In the first place, we believe that planned/approved outages of significant duration, if any, should be evaluated in the planning horizon for those outages that would occur in the planning horizon. These outages should include any seasonal outages or outages that would last for a majority of the season to be studied. We would agree to let the Planning Coordinators/Transmission Planners decide if the outages would be appropriate to include in the models required for assessement. However, from our perspective, transmission equipment outages are not planned beyond the operating horizon and are not planned for peak-load periods which drive system expansion plans. Daily or weekly outages of transmission equipment for maintenance or construction are planned for off-peak periods, and are typically not approved for beyond the

operating horizon. Therefore, the majority of the these outages need not be considered for the planning assessment and should not be a part of TPL-001-5. While it is true that owners of generation equipment plan outages for beyond the operating horizon, these outages for nuclear refueling or regular turbine/generator maintenance are also planned for non-peak load periods. Some transmission maintenance outages are also planned, in the operating horizon, to take advantage of these generation equipment outages to minimize the opportunities for transmission service curtailments. Operations Planning personnel spend hours evaluating transmission system performance considering the various construction and maintenance activities that are proposed to keep the system functioning. These evaluations are performed in the operating horizon for implementation in the operating horizon, and utilize generation redispatch and transmission system switching as part of operating guides to work around the planned outages while considering the next worst single contingency event. We do not believe that the intent of the corrective action plan is to include temporary operating guides that are needed to facilitate near-term construction and maintenance outages. Secondly, if the intent of the proposed change is to address maintenance outages, then the requirement for R2 should be changed to specify the need to study maintenance outages during the times that the maintenance outages would be performed. While it is true that P3 and P6 planning events will not cover all maintenance outages plus planning events for beyond N-2 planning, it would cover a significant reliability concern during these off-peak periods. Thirdly, the Reliability Coordinator (RC) is not an applicable functional entity for this standard. Therefore, we believe that involving the RC in the planning assessment and development of the corrective action plans for long-term system development is inappropriate. The RC has a near-term focus and is often unaware of needed longer-term system developments that are needed to meet TPL-001 planning requirements, as well as local transmission planning criteria. Many of the outages that RCs must address are required for construction or restoration, and likely would not be applicable for future operating conditions.

While we agree with the move away from the 6 month minimum duration outage requirement, we feel strongly that the outages selected by the PC/TP in consultation with their RC should be known outages for the time period beyond Operations Planning time horizon. Required analysis of outages planned in the timeframe within Operations Planning time horizon is addressed in Reliability Standard IRO-017 which are intended to cover the Operations Planning time horizon. Our suggested wording of Requirement 1.1.2 is shown below.	

1.1.2. Known outage(s) of generation or Transmission Facility(ies) as selected by the PC/TP in consultation with the Reliability Coordinator for the Near-Term Transmission Planning Horizon beyond Operations Planning time horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

Comment	

The new requirement is open ended and may result in Transmission Planners (TP) performing almost a "real time" operations analysis (i.e. what is the impact of this outage / what about that outage) in-lieu of designing the Bulk Electric System (the purpose of TPL-001). NERC IRO-017 *Outage Coordination* was set up for that purpose, and this proposed change would represent a spillover from IRO-017. The TP would be required to develop a Corrective Action Plan for system outages.

The new requirement does not address a scenario where the TP does not agree with the RC regarding what needs to be studied, or how such a disagreement would be managed from the compliance perspective. The "limited known outages" statement in Question 1 is not part of R1.

We recommend the Requirements 1.1.2 and 2.1.3 be revised as follows to clarify which entity has the sole responsibility to select the outages (additions in RED):

R1.1.2 Known outage(s) (for the time period beyond 12-months into the future) of generation or Transmission Facility(ies) as selected by the Transmission Planner or Planning Coordinator following consultation with the Reliability Coordinator for the Near-Term Transmission Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

R2.1.3. P1 events in Table 1, as selected by the Transmission Planner or Planning Coordinator following consultation with the Reliability Coordinator, with known outages modeled as specified in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

Alternatively, RC should be removed from these Requirements and TP or PC should have the flexibility to select what needs to be studied; as it relates to outages.

In addition, this new requirement would result in Transmission Planners (TP) or Planning Coordinator performing an annual study as the RC could request a study to review upcoming outages. This could result in a conflict with the existing Requirements that allow the use of past studies to satisfy compliance with TPL-001. While we agree with the move away from the 6-month minimum duration outage requirement, we feel strongly that the outages selected by the PC/TP in consultation with their RC should be known outages for the time period beyond 12-months from the current date. Required analysis of outages planned in the timeframe of less than 1 year from the current date should be the exclusive responsibility of Operations Planning through reliability standards such as IRO-017 which are intended to cover the Operations Planning time horizon. Our suggested wording of Requirement 1.1.2 is shown below.

Scott Downey - Peak Reliability - 1	
Answer	No
Document Name	
Comment	
While Peak agrees that the six month outage threshold should be changed for the reasons described in the rationale provided for proposed requirement R1, part 1.1.2, Peak disagrees with the proposed mechanism of addressing the issues set forth. In accordance with IRO-017-1 requirement R1, the RC is required to have an outage coordination process for transmission and generation outages in its RC Area. This requirement is applicable to the Operations Planning Time Horizon, which is typically considered to be the Time Horizon over which the RC/TOP has assessment responsibility. Outages that are planned further in advance of the Operations Planning timeframe are addressed in the PC/TP's Planning Assessments. These outages are outside the RC/TOP's timeframe of assessment responsibility and are inside the PC/TP's timeframe of assessment responsibility. IRO-017-1 requirement R4, which requires the PC and TP to jointly develop solutions with its respective RC(s) for identified issues or conflicts with planned outages in its Planning Assessment for the Near-Term Transmission Planning Horizon, serves to connect the dots from planning to operations and serves as a valuable hand-off from planning to operations. The requirements in IRO-017-1 were specifically written this way to accomplish the dot-connecting objective. Regarding outages in the planning horizon, the RC has no knowledge of – or responsibilities for – outages that fall outside the Operations Planning Time Horizon. The proposed requirement as written implies that the RC is to have data for planned outages in the Near Term Transmission Planning Horizon and perhaps even to perform some degree of screening to determine which of those planned outages should be included in the PC/TP's Planning Assessments. This not only results in an additional burden for the RC, but also creates an environment where the RC may have (or be perceived to have)	

some degree of responsibility for activities that take place outside of its timeframe of responsibility. Accordingly, Peak does not support the proposed approach of having the PC/TP consult with the RC to determine which outages should be included in the PC/TP's Planning Assessments.

By default, proposed requirement R1.1.2 requires the RC to "do something" in order for the TP/PC to be compliant – which in effect is a requirement for the RC. Peak believes this is not a good approach for writing standards. If the RC does not participate in this consultation, or if the consultation is "weak", is the PC/TP faced with a potential compliance ramifications? If such is the case, is the RC subject to any compliance ramifications? Unfortunately, this same issue exists with currently approved IRO-017-1 requirement R4. While such requirements have a good reliability intent, there are better ways of writing requirements to achieve that desired intent. Bottom line, Peak believes there is a better way.

Peak believes that there are alternative solutions that may better address the issues stated in the proposed R1 rationale box.

One approach could be to create a requirement in TPL-001 or IRO-017 for the PC to develop and implement a process for determining the outages to be included in the PC/TP Planning Assessments for the Near-Term Transmission Planning Horizon. The requirement would have no mention of the RC, so as to not create any implied responsibilities for the RC. That said, if a given PC's process happens to include involvement from the RC, and the RC is agreeable to participating, then so be it. However, Peak does not believe that the RC's involvement under the auspices of "consultation" should be stated in a requirement applicable to PC/TPs. There are pros and cons with this approach.

If an objective is to create requirements to better bridge planning with operations and to have the RC provide input to the selection of outages to be included in Planning Assessments, another approach would be modify IRO-017 to create a requirement for the RC to document the criteria that the PC/TPs shall use to determine which planned outages, at a minimum, need to be included in TP/PC Planning Assessments for the Near Term Transmission Planning Horizon. TPL-001 can then have a requirement to include, at a minimum, the outages that meet the RC's criteria. With this approach, the RC's responsibility would stop with defining the criteria for the PCs to use at a minimum. The RC would not be required to consult with PC/TPs beyond that.

Alternately, the TPL-001 standard itself can explicitly specify the criteria for outages that need to be included in the Planning Assessments for the Near Term Transmission Planning Horizon. If an outage of six month duration isn't the right answer, perhaps the standard can find the right answer and include it in the standard rather than getting the RC involved in the decision process.

Additionally, given the high number of PCs and TPs in the Western Interconnection, it is impractical for Peak as an RC to consult with PC/TPs in the determination of outages that should be included in the PC/TP's Planning Assessments. Given this situation, Peak would be in favor of the second or third potential solutions described above.

Comment	

(1) We are concerned that the proposed changes could require applicable entities to administratively demonstrate communication, coordination, and selection processes for proof of consulting with their RC. This would include a PC-TP selection process that justifies the exclusion of RC-identified outages. The references to Requirement R2 are also cumbersome and require the applicable entity to review other aspects of the standard to determine how to comply with this requirement. (2) We believe the proposed modifications could be simplified to include references to NERC Reliability Standard IRO-017-1, which already requires PCs and TPs to jointly develop solutions for identified conflicts in their Planning Assessments for the Near-Term Transmission Planning Horizon. Near-Term Transmission Planning maintenance schedules identified by TOs and GOs are provided to TOPs and BAs, and then shared with their respective RC, per Reliability Standard IRO-017-1. The RC may have knowledge of future Facility maintenance schedules beyond the Near-Term Transmission Planning Horizon, but only on a voluntary basis as provided by an external entity. We propose this alternative change instead: “Known generation and Transmission Facility outages included in Near-Term Transmission Planning Horizon Planning Assessments for its respective Reliability Coordinator outage coordination process.”

Colby Bellville - Duke Energy - 1,3,5,6 - FRCC,SERC,RF, Group Name Duke Energy	
Answer	No
Document Name	
Comment	

Duke Energy agrees with FERC and NERC that analysis of transmission and generation outages is a critical function that must be performed with appropriate expertise and knowledge to ensure facility outages of limited duration do not create operational concerns. Duke Energy disagrees that these requirements should be included in a planning related standard (i.e. TPL-001). The related requirements would be more appropriate in an operation related standard (e.g. IRO-017). Duke Energy believes an equally effective and efficient solution to address FERC Order 786 can be obtained by modification of an operationally focused standard. Transmission planners ought to be a resource to assist the work in such a standard, but should not have primary responsibility. Inclusion in the proposed standard of the RC in the “consulting” role of making the determination of what outages must be studied is indicative of the fact that operational considerations are key to proper assessment – from what outage to study under what conditions to what are acceptable actions to take to allow the outage to proceed. Operational personnel have the appropriate mindset, tools and background knowledge to perform the assessment and when necessary, be supported by planning personnel. The TPL-001 standard is intended to ensure sufficient infrastructure is planned to provide the operators a robust enough system to operate reliably under the varying conditions they will experience. It would almost never be appropriate to make infrastructure upgrades to alleviate reliability concerns that appear due to outages of limited duration. Transmission planners are expected to evaluate the feasibility of implementation of projects they propose and the outages that will be required as part of developing their TPL-001 corrective action plans. However, the decision to allow outage of any facility for any reason lies with transmission operators. Operating conditions and outage schedules change with time and outage plans must be continuously re-evaluated and revised, up to the very day they are to begin. Conditions change so much that it is not useful nor necessary to study outages throughout the entire Near Term Planning Horizon. The Operating Horizon, usually considered to be 13 months, is a reasonable timeframe for evaluation of proposed outages.

Transmission operators are most knowledgable of system transmission and generation outage plans, how they have changed, the interactions between them, the expected system conditions, what are acceptable compensatory actions for reliability concerns…. and have final authority over allowing an outage to take place. Also, performance of the analysis of outages' impact equips transmission operators to be able to make acceptable last minute decisions regarding outages when expected system conditions change, as they often do. It would be inappropriate to expect transmission planners to make those decisions or to rely to a large extent on analysis that transmission planners had performed in the past for maintenance of system reliability in the operating horizon.

If the requirement is to remain in the TPL standard it should be modified to make it clear that the RC will determine what outages are to be studied and the period to be studied reduced from the full Near-Term Planning Horizon.

Wording in the standard or the technical guidance document should be provided to clarify the RC's role. For example: Outages with a duration greater than 2 months of the same seasonal period or of facilities deemed critical to the operation of the system, in the judgment of the RC, must be evaluated. Such language ensures that the duration of the outage is significant enough to warrant evaluation beyond what will be done under normal operational planning practices. It also allows the RC to exercise their knowledge and expertise when appropriate.

The period that evaluation of such outages should be shortened to the first two years of the Near-Term Planning Horizon. Evaluation of outages further into the future than that will likely result in unnecessary studies being performed by the PC/TP due to changes in outage plans. No reliability gap is created because the outages will be studied prior to their execution.

Although LES agrees with the move away from the 6 month duration outage, we're concerned that the selection of known planned outages in consultation with the RC unduly complicates the process. Recommend removing the RC from TPL-001-5 in consideration that the TP and PC are already performing these assessments and are capable of making a judgment of including or not including a known planned outage.

Additionally, it is unclear whether R1 is intended to be directed towards the annual MOD-032 model development (e.g., where the PC and TPs jointly develop modeling data requirements), or if the selection of known planned outages is solely part of the Planning Assessment.

Texas RE appreciates that Standard Drafting Team's (SDT) efforts to develop a flexible and workable Transmission System Planning Performance Requirement Standard. However, Texas RE is concerned that the current proposal does not properly implement the Federal Energy Regulatory Commission's (FERC) directive in Order No. 786 to include planned outages lasting less than six months in some fashion in the planning process and could result in reliability gaps.

In doing so, FERC provided clear guidance that its intent was to expand the number of planned outages required to be including in TPL-001 planning assessments. Specifically, while recognizing NERC has the flexibility in implementing its directive, FERC specifically enumerated several acceptable approaches that all would result in the inclusion of additional planned outages in the planning process. FERC wrote: "we believe that acceptable approaches include eliminating the six-month threshold altogether; decreasing the threshold to few months to include additional significant planned outages; or including parameters on what constitutes a significant planned outage based, for example, on MW or facility ratings." Each of these scenarios share a common trait: the number of planned outages included in required transmission planning analyses will increase.

In contrast with FERC's examples, the proposed TPL-001-5 could result in the inclusion of fewer planned outages in the transmission planning process. In particular, the proposed standard requires only the inclusion of known generation or Transmission outages that are "selected in consultation with the Reliability Coordinator [RC] for the Near-Term Planning Horizon . . ." Under the proposed TPL-001-5, therefore, Transmission Planners (TPs) and Planning Coordinators (PCs) could elect to exclude not only all planned outages with a duration of less than six months, but also additional planned outages with planned durations greater than six months after consultation. While FERC recognized that NERC should retain flexibility in implementing its directive, the current proposal appears to run counter to FERC's intent to ensure that a broader category of planned outages that could result in impacts to the Bulk Electric System (BES) during peak and off-peak periods are examined to ensure they can occur without the loss of inconsequential load or detrimental impacts to system reliability.

The proposed standard revisions further exacerbate this problem by inserting the same "selected in consultation with the [RC]" language into the scope of the annual Planning Assessment requirements set forth in TPL-001-5 R2.1.3. Under the existing TPL-001-4, Qualified Planning studies must include models of the loss of generators, transmission circuits, transformers, shunt devices, and single poles of a DC line. These P1 contingencies must all be modeled to ensure there is no inconsequential loss of load and no interruption of firm transmission service. In contrast, the revised TPL-001-5 permits TPs and PCs to omit P1 contingencies. Specifically, the proposed standard only required including P1 contingency events selected in consultation with the RC. Presumably, the SDT included this language to flow through its proposed modifications to the six-month threshold in TPL-001-5 R1. In doing so, however, the SDT has again broadened the potential modeling exceptions in R2 beyond merely certain planned outages to permit waivers of all P1 contingencies. As such, it is possible that a TP and/or PC may inadvertently fail to study a significant P1 contingency. However, if that event was not identified in the P1 contingency event "selected in consultation with the [RC]", the TP and PC would still have conducted a qualified Planning Assessment. This result is wholly inconsistent with TPL-001's goal of ensuring BES reliability following a wide range of probable contingencies. Texas RE suggests the gap be addressed by the standard requiring that all P1 events are included in the qualifying studies with known outages modeled.

It is also important to note that the "consultation" model envisioned in the proposed standard could lead to a number of other issues. In addition to the problems regarding the inclusion of P1 contingencies, Texas RE points out that in many instances the relevant PC and RC are the same entity. In the ERCOT region, the same entity is responsible for both functions and develops the initial system-wide transmission models. Accordingly, the proposed standard appears to contemplate this entity "consulting with itself." This raises the possibility that planned outages and other P1 events could be unilaterally excluded from the planning process. Further, it would be difficult for Texas RE to address any inadvertent exclusions or omissions in the planning process under the standard as drafted. Again, this does not appear to be the outcome FERC contemplated in issuing its directive.

Texas RE respectfully requests that the SDT reconsider its approach in light of FERC's directive in Order No. 786 and adopt an approach that broadens the scope of planned outages required to be considered in the planning process. At a minimum, Texas RE suggests that if the SDT wishes to retain the "consultation" model, it should explicitly limit its application to planned outages of less than six months and retain the original bright-line requirements for all other scenarios. Under such an approach, the SDT could revise the existing TPL-001-4 R1.1.2 to read: "Known outage(s) of generation or Transmission Facilities with a duration of at least six months or known outages with a duration of less than six months, as selected in consultation with the RC." Texas RE recommends the SDT further revise TPL-001-4 R 2.1.3 to require that annual Planning Assessments model all P1 contingencies currently in the scope of the existing TPL-001-4 Standard, but again permit those models include planned outages lasting less than six months "as selected in consultation with the RC."

While the 6 month duration may not be an appropriate requirement, involving the RC is not appropriate either. The responsibility of the RC is “operation” of the system. Any outages in the operating time-frame should have been submitted and reviewed prior to approval. Our expereince in long-term outage planning has shown that it is very unlikely that “planned” transmission outages exist beyond the next six months and that generation outages change weekly. Additionally, to move outages that are expected to last a few weeks to two months into cases that can cover 2-4 months is problematic because as you look at the “most impactful” to include in the base system model, the two or three may not overlap presenting another problem for now selecting what to include. If the Standard stated outages that span the duration of the season being studied that would make this straight forward and remove the RC.

The concept of ***planned outages*** needs to have a footnote or further explanation to clarify that this applies to “planned outages needed to execute the CAP” and be very specific.   Maintenance outages should not be addressed in this standard, thus, verbiage should be added to the standard accordingly. Maintenance outage schedules are typically not definitively known beyond 12 months out, and these would be assessed by Operations Planning closer to the desired time of the maintenance outage such that expected system conditions reflected in the study power flow is better known.

If the RC remains included, need to add words to allow the RC’s request to include the exclusion of stability studies of known outages that might impact steady state but clearly don’t impact stability. Examples might be areas of the transmission system that are not electrically close to generation and not in areas susceptible to FIDVR

Comment	

The SPP Standards Review Group would like to clarify an important issue regarding the expectations of regulatory staff on the impacts of Requirement 1, Part 1.1.2. The clarification is about the differences in power flow case topologies used by SPP Operations and SPP Planning. Issues found in the operating horizon would be specific to that point in time and would take into consideration any planned outages, forced outages, generation dispatch, transfers, and load levels that would cause concerns. These operating horizon variables would be changing from minute to hour to day to week to month to season to year. The same outage placed in a planning horizon assessment would be placed into a model that has a lot fewer outages, different generation dispatch, different transfer levels, and different load levels. The topology differences between the two power flow models is significant enough that the operation horizon outages would more than likely not cause issues in the Transmission System Planning Performance Requirements (TPL) Assessment. Further, the SPP Standards Review Group would like to state that trying to mimic, follow, or forecast these operating horizon outages in a meaningful manner would be a moving target. This is due to the fact that most of the planned outages are due to maintenance and capital projects that usually do not re-occur within a 3-5 year period, if ever. The SPP Standards Review Group also finds the proposed language to be vague and ambiguous, regarding the timeframe, and therefore would be hard to defend during an audit.

The SPP Standards Review Group thinks the language is unclear as to whether outages should be evaluated only in the season for which they are planned or whether they should be evaluated for the peak or off-peak 1 or 2, and 5 planning horizon. In addition, The SPP Standards Review Group have a concern in reference to the number of additional cases and the associated seasons that could be required. The The SPP Standards Review Group would like to suggest proposed language that would tie this process to the TOP Standards instead of the TPL Standards as this is pertaining more to operation related issues.

Moving away from the 6 month duration outage to limited known outages mixes clearance coordination studies and daily operational studies with planning studies. This creates planning base cases with outages that may or may not happen. Consultation with the Reliability Coordinator (RC) creates added ambiguity for planning studies.

IID appreciates the effort of the SDT addressing the directives from the Commission on Order No. 786 issued on Oct. 17, 2013, Paragraph 40. This standard is applicable only to PCs and TPs per the Applicability section, thus RCs are not under any compliance burden. So what course of actions can the PCs and TPs take to show compliance if they do not receive due cooperation/consultation from the RCs? Please see the comment under #5 below as well. The changes add extra burden on the PCs and TPs for compliance on which they have no control.

Additionally, the outage coordination seems to be more of an Operational Planning issue (for next-day studies up to six months) than a Transmission Planning issue (one to ten years studies). No matter how far ahead PCs and TPs study the system, when it comes to the Operation horizon, the outages need to be studied again with a more realistic system conditions than in the Planning Horizon. Hence any specific analyses performed by PCs and TPs for the outages in the Planning Horizon don't provide much value to the system operators in the Operation horizon.

Besides, if the system can't meet the performance requirements due to outages as per R2.1.3 and R2.4.3, the TPs and PCs have no other allowed mitigation plans, such as operational procedures, except to recommend Corrective Action Plans which result in capital improvement projects. Thus planning for outages in the Near-term Transmission Planning Horizon will only result in capital investment that effect the rates of our customers unnecessarily.

Instead standard **IRO-017 – Outage Coordination** seems to be a much better place to have this directive from Paragraph 40 of Order No. 786 addressed.

Suggestion: Keep the existing language of R1.1.2 unchanged from TPL-001-4 and address this in a future revision of IRO-017.

Requirement 2.1.3 refers to contingency events (specifically P1 events). Section 2.1.4 already requires sensitivity studies associated with the duration and timing of know Transmission outages. Recommend the following wording: "P1 events in Table 1, with known outages modeled as *determined in accordance with* Requirement R1, Part 1.1.2, uner those System peak or Off-Peak conditions."

LCRA TSC supports the changes in 1.1.2 giving flexibility to each region to determine which outages need to be modelled for planning, however, guidance should be provided in the standard not to require that transmission improvements be constructed for transient outage conditions (outages that are due to construction within a single season or of limited duration within a season for instance).

KCP&L does not support the proposed changes to R1, Part 1.1.2.

The proposed TPL-001 revisions removing the six-month planning time period is without consideration of the expressed scope of TPL-001, to model and study system reliability within the Near-Term Transmission Planning Horizon period which the NERC Glossary defines as 1 to 5 years. Also, the revisions seek to address potential conditions that are better addressed within operational assessments, like TOP-002.

We suggest revisions to R1, Part 1.1.2 not be made.

Expanded Scope

We recognize that the revisions reflect Commission directives but that does not relieve or change our TPL-001 expansion of scope concerns. By removing the six-month modeling threshold, R1 potentially requires modeling that will offer little value in support of BES reliability.

Using planning models to consider contingencies for unusual system conditions is without controversy; however, it is not unusual for issues to appear in real-time system operations that have not been identified in Near-Term planning assessments.

Relevant Variables Not Available for Use in Near-Term and Long-Term Studies

Variables used to develop an accurate study are not available for use in a long-term study: temperature, outages, dispatch, and load and transfer levels. Near-Term planning assessments generally assume some uniform ambient conditions for the area to be assessed. For large RTOs such as Southwest Power Pool, ambient conditions can vary widely across the entire RTO. These system conditions are better assessed in the Operational Planning Horizon.

Of course, Near-Term Transmission Planning Horizon (NTTPH) modeling and actual system operational conditions modeling are both useful; however, unless current operating conditions are considered as part of NTTPH modeling, the modeling does little to protect or improve reliability in the real-time operation of the BES.

Planning Assessment Issue

Proposed TPL-001-5 R1 requires TPs and PCs to maintain system models to perform Planning Assessments; R2 requires completing Planning Assessments. The NERC Glossary defines Planning Assessment as, "Documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies."

Real-time operational conditions are not "…future Transmission performance…" and fall outside the purview of TPL-001. Removing the six-month timeframe from R1.1.2 potentially expands consideration of real-time operational conditions. Such an expansion, considering real-time operational variability within NTTPHs, is inconsistent with the "future" language element identified in the defined term, Planning Assessment.

Maintenance Outages Less than Six Months Pose Little Risk to Reliability

The proposed revisions seem to overlook the fact that planned maintenance outages of less than six months in duration pose little or no risk to BES reliability since they are considered as part of the TOP-002 Standards which use planning variables not available at the time NTTPH studies are completed. Additionally, many planned outages can be taken at times of opportunity when their impact on system operations is reduced.

Examples in Support of Position

Finally, we offer a couple of examples that further support our position: that the proposed revisions to TPL-001 R1.1.2 are already, and more effectively, addressed by real-time operational studies, using variables not available at the time NTTHP studies are completed.

Example 1

In a long range planning study/assessment there might be an exceedance identified for a maintenance outage. Normally, mitigation of that exceedance takes place during near term/real time operational studies. Maintenance outages are impacted/affected more by real-time operational conditions, not some future set of assumed conditions.

Example 2

In the case of outage caused exceedances; they are temporary and typically resolved using operating guides. Also, a Long-Term Transmission Planning Horizon study or a NTTPH study have little value addressing outage caused exceedances which are better addressed when considered closer to the time of the event, allowing the study to consider conditions likely most similar to those at the time of occurrence.

CenterPoint Energy Houston Electric, LLC ("CenterPoint Energy") disagrees with the proposed changes. CenterPoint Energy recommends replacing the proposed language for Requirement 1, Part 1.1.2 with "Outage(s) of generation or Transmission Facility(ies) with a duration of at least six months in the Near-Term Transmission Planning Horizon." CenterPoint Energy's recommendation is based on the following: • Moving away from the six month duration outage goes beyond the intent the Planning Assessment of NERC Standard TPL-001-4. Planned outages less than six months should be evaluated in the Operations Planning time horizon. • Per NERC Standard IRO-017-1 Outage Coordination, coordination is already required between several applicable entities, including the Reliability Coordinator, Planning Coordinator, and Transmission Planner, before any planned outages are included in the Near-Term Transmission Planning Horizon.

Michael Haff - Seminole Electric Cooperative, Inc. - 1,3,4,5,6 - FRCC	
Answer	No
Document Name	
Comment	
The revisions to R1.1.2 and R2.1.3 require the individual PCs and TPs to contact the RC to discuss known outages for long term planning purposes. Seminole is concerned that meeting with the individual TPs and PCs for long term planning of outages is not a function of the RC, and that the drafting team should seriously reconsider the additional requirements it is now placing on the RC, especially since planned outages are already coordinated within the Operations Planning horizon. Additionally, Seminole believes that this requirement should be placed within the existing IRO-017 standard if there is a true reliability need for such coordination; TPL-001-5 is not the correct location for this type of coordination. In R1.1.2, if the RC believes an outage should be included in the System Model and the TP and PC do not believe the outage should be included, what is the process for remedying this problem? Do the TP and PC merely have to show that they consulted with the RC, not necessarily that they came to agreement?

No, there are a few concerns introduced by the proposed modification of part 1.1.2:

· Moving from a firm threshold to consultation creates ambiguity and potential reliability gaps, and is not an effective means to address the FERC concerns expressed in Order 786. when there are no criteria as to how that consultation is to proceed. Further, we do not read FERC's directive on P.40 of Order 786 to mean replacing the 6-month planned outages with other approaches. Rather, we interpret that directive to mean modifying the TPL-001 standard to address the potential impacts of excluding planned outages of less than 6 months in planning assessments.

· Replacing the 6-month threshold with a consultation with the RC has the following potential shortfalls:

a. The TP's/PC's footprint is not necessarily the same as the RC's; there can be several RCs within a TP/PC area, or the other way around. In these cases, who should be consulted and how to reach an agreement if multiple entities are involved? And on what basis should the RC(s) recommend inclusion of certain planned outages?

b. While the draft standard places an obligation on the TP/PC to consult, there is no mirror obligation on the RC to respond. What if the RC does not respond? Is the TP/PC held non-compliant for having no planned outages included in the planning assessment?

c. Two entities may be assessing the same system conditions included the planned outages, but they could come up with quite different assessment results due to different risk tolerances or approaches applied in the assessment. If the TP/PC and the RC, or multiple RCs when more than one is involved, come up with different assessment results, whose results should prevail?

To address the FERC directive without the above potential reliability gaps or shortfalls, we offer the following suggestions:

1. Keep the 6-month planned outage threshold, and supplement it with: Any planned outages that are deemed by the Reliability Coordinator of the concerned facilities to have a reliability impact in the tome frame of the planning assessment being pursued by the Transmission Planner or Planning Coordinator.

2. Add a requirement for the RC to respond to the TP's/PC's request to assess the reliability impacts of planned outages of less than 6 months during the assessment period.

Note: CAISO and ERCOT do not support this comment.

Due to the large number of Planning Coordinators and Transmission Planners in the Reliability Coordinator area, this would be too much of a burden on the RCs to provide appropriate feedback without causing a significant delay or setting the threshhold too low where most if not all planned outages which would significantly increase the time needed to complete the assessment. If the 6 month requirement is removed, the PCs/TPs should provide a reason those planned outages were selected. This would be similar to the language allowing the PCs/TPs to determine which Planning Events are selected to evaluate.

FMPA appreciates the efforts put forth by the SDT to address the Commission directives from Order No. 754 and Order No. 786. We agree with R1 Part 1.1.2 and subsequently with R2.1.3 (steady state analysis). The concern here is that steady state events refer to coordinating with the RC while stability events do not – the implication being that in stability we must study all known outages as opposed to those which are carefully selected. Also, for 2.4.3, explicitly calling out P1 events from Table 1 effectively removes the ability of the PC and TP to apply engineering judgement to study those events that are expected to produce the most significant impacts, and instead adds “busy work”. Furthermore, the extent of that “busy work” is unclear, since if we are required to run P1 events, how many buses away from the affected area must we simulate these? Few P1 events are simulated in stability studies because P2 events at the same buses are almost always more severe. Please see our comments in the General Comment section below.

We disagree with the fundamental premise that there is a reliability need/benefit of studying scheduled transmission outages in the Near-Term Planning Horizon –whether or not they are identified in consultation with the Reliability Coordinator (RC). This is because:

1. scheduled transmission outages almost always qualify as “known” outages only when they are approved/granted by the RC;
2. transition from “prospective” to “known” outages almost always occurs within the operations horizon (0 to 13 months), and
3. very few, if any, transmission outages are approved/granted by the RC well in advance to become “known” outages in the Near-Term Planning Horizon.

Consequently, we assert that deleting Part 1.1.2 from the standard will not have any adverse impact on the planning assessment of future BES reliability.

However, if the SDT is not persuaded to delete Part 1.1.2, we recommend improvements to the verbiage in Part 1.1.2 to address the ambiguity and lack of detail associated with what comprises “consultation with the Reliability Coordinator”.

Further, it is also ounclear why scheduled outages that are “known” would nevertheless have to be “selected” in consultation with the RC – wouldn’t *all* outages that are scheduled/approved by the RC for Year One through year 5 time horizon qualify as “known” outages to be included in the analyses (and hence no selection)?

NERC should provide a clear directive to the RC, where the RC provides a list (in a timely manner to complete the assessment) of know outages to the TP, only after the RC coordinates with the TO for transmission outages and with the GO for generation outages. The TP/PC do not own any assets nor are they aware of predetermined maintenance schedules required by both the TO and GO. Additionally, if TOs, GOs, etc. actively participate as required by MOD-032-1, these known outages would be captured for the respective seasonal time frame.

We suggest the SDT looks at the recommendations in NERC SAMS white-paper on Order 786 for guidance in the case that 1.1.2 is revised.

Long Duong - Public Utility District No. 1 of Snohomish County - 1,4,5	
Answer	No
Document Name	
Comment	
Obtaining known outage(s) or Transmission Facility(ies) through the RC for the Near-Term Planning Horizon may be difficult for PCs and TPs, unless the RC has a maintained and approved list of known outages for TPL studies. To sort out applicable outages for the Operations and Planning studies would be a burden for the RC. Additionally, the expectation for the PC/TP to read and extract that information from the RC's maintained and approved list of known outages, is impractical. Therefore, SNPD suggests the Drafting Team remove any language that requires consultation with the RC and we recommend restoring the original language to Requirements 1.1.2 and 2.1.3 and restating "Known outage(s) of generation or Transmission Facility(ies) with a duration of at least six months." If/when the Drafting Team prefers to have a lesser duration than six months, as required by NERC staff, we would support a duration of at least 3 months, for "Known outage(s) of generation or Transmission Facility(ies) with a duration of at least three months."

Comment	

The proposed coordination of outages with the RC forces a merging of two disconnected timeframes, and reduces the RC's focus on operational activities. The prescribed 6-month outage duration in the current standard provides a clear separation between the Operations Planning Horizon and the Near-Term Planning Horizon. Furthermore, asking the RC to be directly involved in the near term planning horizon expands on their defined purpose as documented in the NERC Rules of Procedure. It is unclear what types of outages are to be considered under 1.1.2. SRP recommends clarification on what types should be considered e.g. breakers, switches, etc. It is unclear what "consultation" means. If the SDT retains the proposed changes, SRP recommends the SDT clarify what level of coordination is required.

Comment	

The NSRF recognizes the TPL drafting team is attempting to address a directive from FERC Order 786 in a reasonable and flexible manner. It's the NSRF's understanding that FERC expressed concerns about maintenance outages of equipment that could not be taken out-of-service even at low load levels. The NSRF agrees if there are known or demonstrated important BES generators, lines, transformers, or bus sections that cannot be taken out-of-service even at Off peak load levels, a Corrective Action Plan (CAP) seems apprpriate. The RC or TP could list the known or demonstrated Element on a corrective actions list for the TPL standards similar to PRC-023 and R6. Any newly identified Protection System should have a similar study and implementation period clearly outlined in the standard if possible. There are concerns that Reliability Coordinators do not have (1) an adequate venue for consultation on selecting outages and (2) knowledge of outages with sufficient lead time (36 or 60 months advanced knowledge) to perform the required assessments and implement resulting Corrective Action Plans.

1. IRO-017-1 already requires the RC to maintain a coordination process for the Near-Term Transmission Planning Horizon. The proposed approach in TPL provides little guidance to the RC/TP/PC as to what level of detail to model future outages. This may lead to widely varying practices across regions. 2. We support the other approaches suggested by FERC to limit the scope based on both time and outage significance. The proposed alternate for R1.1.2 is: Schedule outage(s) of Generation or Transmission Facility(ies) that are identified by the Reliability Coordinator, Planning Coordinator, or Transmission Planner as critical to the derivation of Interconnection Reliability Operating Limits (IROLs) and lasting longer than 90 days. 3. It is important to note the difference between a planned outage in the sense: (1) that maintenance crews "plan" for insulation testing of every transformer every three years, and (2) that a nuclear plant plans to be offline for refueling from exactly 3/3/2019 @ 19:30 to 9/15/2019 08:00. In the former case, the exact outage dates are both unknown and highly flexible, whereas with the latter the outage has specific dates that can be modeled and it must occur regardless of system conditions. The previous 6 month limit served as a screen to identify only those outages which were likely to occur during critical system conditions. Most maintenance is scheduled to avoid system peaks. 4. It unclear how to model planned outages in year one, year three or year four if the TPL planning assessment uses year two and year five.

2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?	
Amy Casuscelli - Xcel Energy, Inc. - 1,3,5,6 - MRO,WECC,SPP RE	
Answer	No
Document Name	
Comment	
We do not see any reliability gap in the existing standard TPL-001-4 due to the absence of Part 2.4.5. This is because, based on our operating experience, the unavailability of long lead time spare equipment (typically auto-transformer and shunt reactor) has rarely, perhaps never, resulted in unacceptable stability outcome. That is, the risk for instability in BES due to unavailability of spare equipment is minimal, if not negligible. And any BES vulnerabilty to unacceptable stability performance will get adequately assessed when performing stability analyses for P3-P6 Planning Events. Consequently, there is minimal, perhaps even negligible, incremental benefit to be realized by performing additional stability analyses for P1 and P2 events by using prior facility outage as the proxy for unavailability of long lead time equipment failures. Therefore, we do not support the addition of Part 2.4.5 in the draft TPL-001-5 standard.

Similar to the comments entered for question 1 above, explicitly requiring that P1 events be simulated now removes the ability to apply engineering judgment. P1 events would not normally be studied in stability since P2 events at the same buses would produce more severe impacts. In addition, explicitly	

calling out items from Table 1 introduces the ambiguity of how many locations must be studied, since in stability, unlike steady state, it is not feasible to study events at every bus in the system. Please see our comments in the General Comment section below.

The word “studied” should be changed to “assessed” or “evaluated” (and the same change should be made in Part 2.1.5.) Overall though, we’re more interested in the change for 2.4.5 since not all equipment that’s part of a spare equipment strategy would require stability simulations (e.g. a reactor), whereas steady state analysis is more commonly applicable	

Note: ERCOT does not support this comment.

If FERC requires the standard to address spare equipment for dynamics, there should be language that makes it clear that if the non-spared equipment is far away from where the dynamics contingencies are being simulated (i.e. generating stations) then it does not need to be considered. Dynamics contingencies aren't run system-wide like loadflow.

The possible unavailability of long lead time equipment can result in the thermal or voltage planning criteria violations but not on the transient stability of the BES. Hence adding this requirement will burden the PCs and TPs with extra work with no significant improvement in the reliability of BES. Suggestion: Requirement 2, Part 2.4.5 is not needed.

Need some verbiage to allow for the exclusion of studies of unavailable equipment that might impact steady state but clearly don't impact stability. Examples might be areas of the transmission system that are not electrically close to generation and not in an area susceptible to FIDVR. An extra sentence "Detailed stability assessments are required only for scenarios where a stability impact could be possible as a result the unavailable equipment" or something simiiar would be appropriate.

PG&E agrees with the addition of part 2.4.5, however we believe that more details and clarification on the selection of the transmission equipment, and P1 and P2 contingencies is needed. It is recommended to add language that defines what “major Transmission equipment” would require a stability study. We also offer the the following change to the selection of the P1 and P2 categories from Table 1: “…The studies shall be performed for the P1 and P2 categories identified in Table 1 **[that are expected to produce more severe System impacts on its portion of the BES],** with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.”

ERCOT recommends removing P1 events from Part 2.4.5. The current TPL-001-4 standard already requires entities to evaluate P6 events, which produce the same contingency results that studying P1 events would produce assuming unavailability of long-lead time equipment. It is unnecessary to require the proposed analysis in Part 2.4.5.

NVE is concerned that the scope of this requirement is infeasible. Depending on the amount of spare equipment available, to add dynamic analysis for P1 and P2 events for each unavailable spare, could result in a large number of contingency cases to run. Depending on the number of cases to run, there could be significant resource or run-time issues. As a specific example, it takes approximately 3 weeks for NVE to compute (run) stability analysis on a single model. For 20 pieces of BES equipment without spares, it would push the run-time for all P1 and P2 events to far beyond 1 year, not including time for analysis of the results by staff. NVE recommends allowing the transmission planner to select which P1 and P2 events should be run for each unavailable spare, rather than all P1 and P2 events.

Steady state analysis per sub-requirement 2.1.5 of the TPL-001-4 standard should be able to capture any thermal or voltage concerns when spare equipment is unavailable due to long lead time. Revising the sub-requirement 2.4.5 to include stability analysis to unavailable equipment due to long lead time potentially adds significant workload without adding any more value than the results of steady state analysis. Suggestion: Retain the existing language in sub-requirement 2.4.5 of the TPL-001-4 standard.

Order No. 786 does not appear to order, or direct NERC, to change TPL-001 to include stability analysis as part of the spare equipment strategy assessment [see page 58 of Order No. 786]. FERC directed "…NERC to consider a similar spare equipment strategy [as steady state] for stability analysis". SDG&E agrees with NERC's original comments found in Order No. 786 that additional stability assessment will not yield meaningful information and provide a significant reliability benefit. SDG&E recommends removal of section 2.4.5.

Logically, this modification makes sense. However, in practice, this modified requirement is somewhat redundant with Table 1, P3 and P6 events. P3 and P6 events are applicable for stability analysis. The additional study burden may not be commensurate with the expected incremental reliability benefit. For stability analysis covering P3 and P6 events, the initial event (i.e. element or facility outage) is carefully selected to be a impactful outage. In practice, existing study procedures related to P3 and P6 events are a good proxy for the assessment of unavailability of long lead time equipment. We would encourage the SDT to inquire about existing study practices for P3 and P6 events (from the REs and the ISO's) to assess if those existing study practices satisfy the intent of the proposed Req # 2.4.5.

The SPP Standards Review Group agrees with drafting team adding the new sub-part of Requirement R2 to address the spare equipment issue in the stability assessment. The SPP Standards Review Group would like the regulatory bodies to consider adding language in the Steady-State Assessment area of NERC Standard TPL-001 to address the Stability Assessment of the spare equipment strategy. This would mean that if a spare equipment strategy caused issues in the Steady State Assessment, it would prompt the Transmission Planner (TP) and Planning Coordinator (PC) to perform additional Stability Assessments for those specific issues.

Corn Belt agrees, but suggests that "more than 1 year" be substituted for long lead time throughout TPL-001-5 where appropriate for better clarity. Concerns that the number of additional dynamic analyses to include long lead time items taking more than 1 year for P1 and P2 needs to be bounded. There are real computational constraints that could take months to run. An example could give the Transmission Planner discretion to chose the worst conditions.

3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?	
Leonard Kula - Independent Electricity System Operator - 2	
Answer	No
Document Name	
Comment	
While the revised footnote is an improvement, clarifications are still needed to properly identify the redundancy requirements. We believe that minimum design requirements should be included in the standard. That will allow the Planning Coordinators/Transmission Planners to have a consistent interpretation of the footnote 13. The following questions demonstrate the ambiguity around redundancy: - Is it allowed to have two control circuitries that use different wires but share the same control cable? - Do the trip coils need to be monitored? There are situations when non BES elements are connected to BES buses (e.g. radial circuits supplying loads). The standard must clarify which protection systems failures needs to be studied since an uncleared close in fault on a non BES element connected to a BES bus has the same consequence as an uncleared close in fault on a BES element. Do the protection systems installed on non BES elements connected to BES buses and protecting portions of the BES buses need to meet redundancy criteria?

General recommendation: Footnote 13 should be carefully reviewed and modified (or expanded), as necessary, to be consistent with the Rationale for the modified P5 event, and also consistent with the NERC Glossary definition of “Protection System”. Enough detail should be provided in the footnote to ensure clarity of what needs to be considered.

Footnote 13.1 mentions “A single protective relay”. As written, this does not provide sufficient detail for the planner or protection engineer to focus on. The term protective relay needs to be clarified. For example, could this include auxiliary relays such as lock-out relays that are used for tripping (function 86)? Alternatively, does this non-capitalized term only apply to relays that operate on or respond to measured electrical quantities such as current and voltage? Additional clarification is required to allow the planner / protection engineer to be completely focused on what is required for compliance.

The rationale mentions that the scope of consideration should be limited “to those relays that are used for primary protection at the local terminal…”. What is meant by “primary protection”?

Footnote 13.4 needs clarification. For example:

- Does 13.4 mean that redundant relays tripping through a single wire to a single trip coil would constitute a non-redundant component of a Protection System?

- Does 13.4 mean that redundant relays tripping through a single trip coil would constitute a non-redundant component of a Protection System?

Considering the complexities of 13.4, sample, or representative protection system diagrams that would constitute examples of non-redundant components of a Protection System would be helpful. Such diagram(s) would provide clarity in a similar fashion as the diagrams provided in the NERC BES Reference Document.

A general concern here is that this modified footnote, as written, is very confusing. The confusion imposed, along with the additional study burden, may not be commensurate with the expected incremental reliability benefit.

Finally, we would note for consideration, that failure of a non-redundant component of a Protection System could result in not only increased total fault clearing time, but also an increase in the number of elements that must be tripped to clear the fault. It is recommended that the Rationale section be modified to mention this additional reliability implication.

Comment	

We disagree with the inclusion of the communication system component to Table 1 footnote 13. A single point of failure in a communication system component poses a lower risk for delayed clearing for a variety of reasons and should not be included in footnote 13 as stated by the NERC SPCS/SAMS Order 754 report. Analyzing these risks in planning studies provides significant additional burden for limited gain in reliability.

We understand the SDT's reasoning but urge them to reconsider as this will add a whole new level of detailed analysis by the entities which will lead to a lot of questions requiring guidance from the SDT to ensure consistent application continent-wide.

Basis for our position

To effectively analyze a single point of failure (SPOF) in communication systems the protection schemes used to protect the element and operation of these schemes need to be considered. Looking merely at common hardware, common circuitry and a common communication path is not enough to determine if a single point of failure exists. For example a common communication path can be used for both System A protection via a Directional Comparison Blocking Scheme (DCB) and System B protection via Line Current Differential. If the common communication path fails and a fault then occurs, the DCB scheme will trip with no intentional delay and clear the fault (proper communication system function is not needed). DCB misoperation (overtrip) is associated with faults outside the zone of protection and thus is not associated with delayed clearing as specified in Table 1. Eversource would contend that this is not a single point of failure. Does the Drafting team and the rest of NERC agree?

If communication systems are to be included in footnote 13, considerable additional guidance will need to be included in the standard to ensure only the correct consistent application of SPOF continent-wide. The proposed footnote 13.2 states "A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported."

{C}·   What does "not monitored or not reported" mean? If an entity performs a manual carrier check-back test once every 4 months, which is allowed for unmonitored protections system communication system component maintenance per PRC-005, is that considered monitoring or is that "reporting" for the purposes of this standard? Most carrier systems utilize automatic check-back functionality in which case the communication path and end enquipment is checked once a day. Is that frequent enough to be considered "monitored"? PRC-005 uses the following definition for a monitored communication system: "Any communications system with continuous monitoring or periodic automated testing for the presence of the channel function, and alarming for loss of function". Alarming criteria in PRC-005 is specified as : "Alarms are reported within 24 hours of detection to a location where corrective action can be initiated."

{C}·	Is having System A and System B protection communication paths share a common structure a single point of failure, such as a common microwave tower? NPCC Directory 4 does not count this as a recognized single point of failure.

{C}·	Is having System A and System B protection communication paths utilize third party leased communication path a common point of failure even if the third party claims they are diverse (two leased phone lines). NPCC Directory 4 would discourage this and claim that it is not an effective diverse path.

We agree that today, most entities do enable continuous or periodic automated testing of their communications system components and do alarm them to a 24/7 montiored control center where action can be taken. Therefore, we feel the effort to correctly defined and identify the small number of unmonitored communication systems that correctly meet the SDT intent, as it applies to delayed fault clearing, is overly burdensome relative to the reliability benefits.

Russel Mountjoy - Midwest Reliability Organization - 10, Group Name MRO NSRF

Answer	No
Document Name	

Comment

No. The NSRF recommends that “Cascading” be replaced with a specific MW number such as the loss of 2,000 MW of generation as referenced in the EOP-004 standard. The term “Cascading” remains too vague and subject to change. A MW threshold is a better “bright line” criteria.

The NSRF recommends each BES Protection System component class be covered explicitly in Footnote 13 along with an inclusion or exclusion justification. Abrief Protection System scope for Footnote 13 may also be helpful.

The NSRF asks if relays should be limited to electromechanical relays as the SPCS/SAMS Order 754 report identified risk depends upon the relay type and protection system design (meaning multiple relays to respond to a fault). If an entity shows no electromechanical primary or aux relays can that be sufficient to exclude from being redundant?

The NSRF asks if communications systems should be eliminated except for RAS. The SPCS/SAMS Order 754report identified communications systems posed a lower risk level.

Example NERC Defined Protection System Component Classes, Scope and Applicability:

NERC Bulk Electric System (BES) protective relays/sudden pressure relays/reclosing relays:

NERC BES PRC-005-6 Protection System electromechanical primary and auxillary relays are included in footnote 13. This includes PRC-005-6 identified sudden pressure and reclosing relays.

NERC BES associated communication systems:

NERC BES PRC-005-6 associated communication systems are included in footnote 13.

Redundant communications system for footnote 13 would be two communications channels. Redundant communications for Footnote 13 does not require separate and diversely routed communications towers.

NERC BES Voltage and current sensing devices:

NERC BES PRC-005-6 voltage and current sensing devices are not included in footnote 13. The SPCS/SAMS Order 754 report identified that voltage and current sensing devices were robust and posed a lower risk level.

NERC BES Station batteries:

NERC BES PRC-005-6 Station batteries are included in footnote 13 with the following exceptions. A single station DC supply is allowed if monitored for low voltage and open circuit alarms to a centrally monitored location within 24 hours of abnormal condition detection.

NERC BES Battery Chargers:

NERC BES PRC-005-6 station battery chargers are included in footnote 13. A single station charger is allowed if the battery bank is monitored for low voltage and open circuit alarms to a centrally monitored location within 24 hours of abnormal condition detection.

NERC BES DC control circuitry:

NERC BES PRC-005-6 DC control circuitry is included in footnote 13 but its outcome is already considered in the P4 stuck breaker category. Whether stuck breaker of a DC control circuit failure, the end result is the same.

Steady-state and stability software cannot not model directly the non-redundant components listed in footnote 13. Instead, the transmission planning engineer must simulate a component failure by deciding how the protection system will respond to the failure (which circuit breakers open and which don't) to clear the fault. Therefore, the engineer, not the software, will determine how the failure is simulated. For the purposes of the standard, the engineer may limit the Category P5 protection failures to those components found in footnote 13 and ignore any other possible single component failure. SDG&E recommends removal of footnote 13 and simplification of the P5 language to read, "Multiple Contingency (Fault followed by a protection failure resulting in multiple elements removed from service)". This would require that a fault followed by a protection system failure be assessed without consideration of protection system redundancy. If an issue is found, then the existing protection system would be reviewed for redundancy. If no redundancy exists, then addition of a redundant protection system can be part of the Corrective Action Plan. SDG&E recognizes that some TPs and PCs may object to doing protection failure simulations of fully redundant systems, but additional simulations can only improve system reliability.

While AEP does not object to the concept itself of adding "communication system" to footnote 13, we believe its inclusion goes beyond the scope of the current SAR. We believe such an inclusion should not be considered until the SAR has been appropriately revised, and industry afforded opportunity to provide comment on the suggested change. AEP requests additional clarification of footnote 13.4 regarding the phrase "through the trip coil(s) of the circuit breakers or other interrupting devices." In the data request associated with FERC Order 754 (Single Point of Failure on Protection Systems), local breaker failure protection was allowed to be modeled in cases of non-redundant trip coils. AEP recommends either changing the proposed text to allow the consideration of local breaker failure protection for trip coil failure (which has already been studied in P4), or instead, the elimination of the phrase altogether.

While we agree with the clarification of components of a Protection System, we would like to see further clarification under P5 and the new Extreme Events (2e through 2h) as to where the fault and the failure of the components of a Protection System occur.

Is the intent of these new faults to have the fault and the failure of the component of the Protection System locally, remotely, or both?

Can this be added ("**local** failure of a non-redundant component of a Protection System", or "**remote** failure of a non-redundant component of a Protection System", or "**local and remote** failure (not simultaneously) of a non-redundant component of a Protection System") to the P5 and Extreme Events?

A fault locally along with a local failure of a component of a Protection System would be similar to NPCC's Criteria A-10 test, however, a fault locally with a remote failure of a component of a Protection System would be a scenario new to the industry, possibly leading many entities to discover scenarios where they have uncleared faults, however this may not be apparent to entities to be studied unless it's clarified in the standard.

1) Clarity needs to be added to “single relay” to exclude instances where a second relay performing a different function is also installed.

2) Clarity needs to be added to “single communication system” to specify the devices that need to clear a fault as opposed to devices that may result in overtrip.

3) Clarity should be added to allow for redundancy provided by devices responding to non-electrical quantities.

4) Clarity should be added for what constitutes “not monitored” or “not reported” in the instances of communication system and DC supply.

5) Clarity that redundant trip coils are not required.

The SPCS report on single point of failure did not include “a single communications system, necessary for correct operation of protective functions, which is not monitored or not reported”. The SPCS concluded that analysis of communications systems with regard to single points of failure did not pose enough of a risk to warrant addition in footnote 13. This assessment was based on SPCS efforts over the years studying blackouts/significant events and their causes. Communication system failures were not a causal factor in the significant events studied by the SPCS. Failures of relays and auxiliary relays have been causal in significant events. Thus, we agree with the SPCS assessment. We do agree with the drafting team that the vast majority of communications systems are monitored 24/7 to a central location. The few unmonitored systems on our system are applied at HV voltage levels where consequences of slow clearing are much less significant. PRC-005 already requires that unmonitored communications systems be tested on a frequent basis. In our case and likely for many others, this is sufficient motivation to create a program to add monitoring to unmonitored communications systems. All of these items relegate the addition of communication systems to footnote 13 to an exercise in documenting the low number of communications systems that are unmonitored. This addition then becomes purely burden with very little if any affect on our goal of providing an adequate level of reliability for the power system. Thus we recommend removing communication systems from footnote 13 in the revised standard.

WAPA agrees with the intent but offers improvements to the language.

In Order No. 786 (P69), FERC declined to direct that NERC revise this standard to apply to all protection system components, at least until NERC completed its analysis of the Order No. 754 data responses. After review of that data, the NERC SPCS and SAMS recommended including protective relays, DC control circuitry, and station DC supply in the standard. This recommendation was based on the survey results regarding the prevalence of non-redundant protective equipment and the simulated disturbance magnitude of a failure of non-redundant equipment. The SPCS and SAMS report, did not, however, quantify the likelihood of each type of non-redundant protection component failure. Thus, it is hard to fully agree with the SPCS/SAMS recommendations at this time (and the Standard Authorization Request is only to “consider” them rather than “address” them).

WAPA does not believe that it is necessary to include analysis of all of these non-redundant Protection System component failures in the TPL standards at this time. Alternatively, if they are included, then they should be treated similarly to the current treatment of Extreme Events where there are no strict performance requirements or mandates to create Corrective Action Plans. In fact, the SPCS and SAMS report suggested that auxiliary relay and lockout relay failures were the main culprit in previous disturbances but failures of other equipment are generally rare or unimpactful (p.7). If anything, the P5 category expansion should be limited to auxiliary and lockout relays. This would allow utilities to focus their money and attention to mitigating the most severe potential impacts rather than building redundancy into systems where it will most likely never be needed.

WAPA recently studied the cost of eliminating single points of failure at a typical older substion. WAPA estimates that building full redundancy will likely cost over $1.3 million and take about a year and a half to implement. The main reason why it takes this long is due to scheduling outages. During outage timeframes, WAPA may have to curtail transmission or generation schedules, which many WAPA customers and staff would view as a decrement to reliable operations. The commissioning of new relays also requires significant testing, which conceivably puts WAPA at greater risk for human error. Furthermore, WAPA does not have any record of a P5 or EE2d type of event in the last 50+ years. Just building redundancy into substations will be a challenge to explain to WAPA ratepayers, and it may prove extremely difficult if WAPA is required to add costs and time for DC control circuitry equipment. Instead, WAPA may desire to focus its limited resources on developing replacement plans for aging equipment (e.g. transformers) or improving security measures.

As a reference, here is the language from SAMS Table 1.3. *DC Control Circuitry: The protection system includes two independent DC control circuits with no common DC control circuitry, auxiliary relays, or circuit breaker trip coils. For the purpose of this data request the DC control circuitry does not include the station DC supply or the main DC distributionpanel(s), but does include all the DC circuits used by the protection system to trip a breaker, including any DC control circuit (branch) fuses or breakers at the main DC distribution panel(s).*

In addition to the concerns mentioned above, WAPA suggestions the following clarification of components of a protection system (Footnote 13).

Suggested Language:

For purposes of this standard, non-redundant components of a Protection System to consider are as follows:

1. A single protective relay which responds to electrical quantities used for primary protection;

2. A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported;

3. A single DC supply associated with protective functions that is not monitored for both low voltage and open circuit, with alarms centrally monitored;

4. A single DC Control Circuitry that causes the primary and local backup protection system to not operate properly and triggers remote delayed clearing.

Comment

PGE does not agree with the inclusion of Footnote 13.3 *A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit.* It is PGE's interpretation that this requirement is intended to address the potential failure of a

station battery when called upon to operate. The language in the footnote does not address monitoring the health of the battery, but instead addresses monitoring the battery charger. Monitoring voltage of a battery is really monitoring the operation of the battery charger. A functioning battery charger can mask a failed battery. Discharge testing of a battery is the only known reliable way to assess the batteries health. PGE does not agree with the inclusion of Footnote 13.4 *A single control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.* Table 1 requires that breaker failure be studied under Category P4. It is unclear how this footnote will add benefits and clarity to the TPL standard.

The further clarification is useful for the most part with one exception. SCE proposes that footnote 13, part 4 include an exclusion for single control circuitry with monitoring as done for parts 2 and 3. Currently the PRC-005-6 supplemental reference allows for maintenance programs to use both traditional time-based maintenance (minimum periodic intervals) and condition-based maintenance (continuously monitoring for inoperable components) to pre-emptively identify protection system issues and satisfy FERC's protection system verification directives from Order 693. SCE believes that trip coil/control circuitry monitoring should not only adequately mitigate any reliability risk that footnote 13, part 4 tries to capture, but can also be used in Corrective Action Plans where single control circuitry is not monitored and assessments demonstrate an impact to reliability. SCE recommends the following language for footnote 13, part 4: 4. A single control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices, which is not monitored.

IEEE recommended practices are used in designing typical generator protection schemes. Prevailing protection schemes (based on IEEE Standards) for a majority of generators that are in service may not have completely redundant protection schemes as clarified by proposed footnote 13. It may not be practical for GO/GOP to implement a completely redundant protection scheme. For example, it may not be physically possible to install additional CTs on the generators or redundant battery systems. The Standard Drafting Team should develop an application guideline with appropriate figures to clarify the Standard Drafting Team's goal with this clarification. Refer to Figure 1.1 of NERC Technical

For P5, the probability of the occurrences of these component failures do not warrant a planning event. NIPSCO believes the current set of Planning events encompass the most likely to occur protection component failures, therefore P5 should remain as is. NIPSCO believes the addition of these components, specifically the single dc supply, will involve most BES facilities. This will create more extreme type contingencies involving loss of a complete substation. With most BES substations not having redundant protection components as the proposed footnote lists, the mitigations will result in unreasonable costs that were not intended by the standards or FERC Order 754. If these components are to be considered, it should remain as an extreme event.

Footnote 13 requires some changes. First of all, the P5 contingency event description clearly indicates that the P5 contingency only covers situations where there is “Delayed Fault Clearing due to the failure of a non-redundant component of a protection system to operate as designed”. Therefore, it should be clarified in footnote 13 that any single component failure that results in overtripping , but not delayed fault clearing, should not be considered in the P5 contingency. For example, this would eliminate a single communications channel failure in a directional comparison blocking scheme (very common scheme for transmission line protection) from being considered a single-point of failure since this failure would result in overtripping, but not delayed fault clearing. However, a single channel communications failure for a permissive overreaching transfer trip scheme would be considered a single component failure since such a failure could result in delayed fault clearing.

Second, there is no mention of instrument transformer failure as a single component failure, but such failures could directly result in a failure to trip and thus subsequent reliance on delayed remote backup protection to clear the fault. A NERC technical paper titled “Protection System Reliability – Redundancy of Protection System Elements”, which was prepared by the NERC System Protection and Control Task Force and dated November 18, 2008, correctly indicates that instrument transformers can represent a single point of failure in a protection system as follows:

From Section 5.1 of the technical paper: “At least two isolated and separate AC current sources (referred to as CT inputs) for Protection Systems are required to meet the proposed requirement for CT redundancy. Figure 5-3 shows a common arrangement that addresses the current measurement redundancy requirement. CTs are required to provide totally separate secondary AC current sources for each redundant Protection System. This is required so that a shorted, open, or otherwise failed CT circuit will not remove all protection elements requiring current.”

From Section 5.2 of the technical paper: "At least two separate secondary windings supplying voltages for Protection Systems are required to meet the proposed requirement for AC voltage source redundancy when such voltage sources are required to satisfy the BES performance required in the TPL standards. This is required so that a shorted, open, or otherwise failed voltage circuit will not remove all protection elements requiring voltage."

The proposed requirements outlined in the NERC technical paper align well with how most transmission owners have historically developed fully redundant protection schemes, and thus should be incorporated into Footnote 13 of the proposed TPL-001-5 standard.

Footnote 13 should clarify that a single protective relay means a single protective relay unit and not a single protective relay element. For example, a digital relay with multiple elements could experience a power supply failure, thus removing the functionality of all elements included in the relay unit. Therefore, using two relay elements in a single protective relay unit would not provide single-point-of-failure redundancy.

Footnote 13 should clarify that DC control circuitry specifically includes auxiliary relays and lockout relays, since such relays have often been the cause of single-point-of-failure events in the past. Furthermore, footnote 13 should clarify that only those DC control circuitry failures that do not result in merely a breaker failure operation should be checked. For example, if a circuit breaker includes only a single trip coil, but the DC circuitry that energizes the trip coil from redundant protective relays is isolated from the DC circuitry that initiates breaker failure from the same redundant protective relays via different output contacts, then a single trip coil is clearly part of the breaker and not part of the protection system since a failure of the trip coil results only in a P4 stuck breaker contingency (i.e., it would not cause a failure to initiate breaker failure, only a failure of the breaker to trip).

Also, the SDT may want to consider clarifying in Footnote 13 that only DC control circuitry associated with tripping circuit breakers should be considered when assessing whether or not there are single points of failure. That is, DC control circuitry required to close the circuit breaker would not cause delayed fault clearing through failure to trip, and should be excluded from the list in footnote 13.

The parenthetical that specifies the different relay types should not be deleted because the term “single protective relay” is not specific enough. Also, the definition of the word “reported” included in the Rationale box should be moved to the footnote to make clear what “reported” means in numeral 3. As proposed, these sentences should read: 2. A single communications system, necessary for correct operation of protective functions, which is not reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated. 3. A single dc supply associated with protective functions, and that single station dc supply is not reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated for both low voltage and open circuit.

PacifiCorp agrees that additional footnote regarding further clarification of relay to components of a Protection System is helpful, but would request the drafting team to further clarify note 13 subpart 1 that the Transmission Planner include in the analysis only those single relays that are associated with isolation of fault. PacifiCorp believes that the note should be written as **“1. A single protective relay used for isolation of fault “** Similar to comment above, note 13 subpart 2 should also clarify that communication required to isolate a fault should be redundant or monitored and reported. Also clarification as to what monitoring and reporting for the single communication systems should be performed to eliminate that as part of non-redundant protection system component would be helpful.

We appreciate the attempt to further clarify the non-redundant components of a Protection System. However, from a planning perspective, it makes no difference as to why or what portion of the Protection System failed to operate and results in the delayed clearing. We are typically more interested in the most severe fault with the longest clearing time or the longest time delay. This change, if adopted, will likely require a change in our philosophy of running the most severe contingencies for each of the major substations, to running all contingencies to identify possible violations. This change as proposed will require a significant increase in stability analysis, and for very little benefit.

Payam Farahbakhsh - Hydro One Networks, Inc. - 1,3	
Answer	No
Document Name	
Comment	
If the drafting team decided that the listed four items in Footnote 13 define single points of failure of Protection Systems, Hydro One suggests revised language in order to provide clarity for both the Planners as well as the P&C SMEs who will be called upon to evaluate the Protection Systems. We suggest the wording in the standard be clarified either directly or through appropriate descriptions in the rationale boxes. We also note that the 4 items in the footnote seem to be a mix of truly redundant components or singular components whose health is monitored. True Protection System redundancy to avoid single point of failure does not depend solely on health monitoring to meet redundancy requirements. We note and reference a previous work by the NERC SPCS concerning protection system redundancy entitled Protection System Reliability – Redundancy of Protection System Elements" (November 2008) where much of the wording in Footnote 13 and the corresponding rationale was derived from.	

Please consider the following comments and suggestions:

1. Table 1 Footnote 13.2 – (Also, reference Section 5.4 of NERC SPCS report)

Please clarify if the intent that a single monitored communication system necessary for correct operation of protection functions means that a single communication channel which is monitored meets the redundancy requirement. Quoting from the NERC SPCS report identifying redundant teleprotection schemes:

Some acceptable communication schemes are:

• Two power line carrier systems coupled to multiple phases of the line.

• Two microwave systems and paths with multiple antennas on a common tower.

• Two fiber paths between terminals (two fibers in the same cable are not acceptable)

• Two separate communication systems of different technologies and equipment (e.g., fiber

optic and digital microwave).

It would appear from the draft wording for this footnote that any singular communication channel, as long as it is monitored, does not need to be considered in the planning assessment. Please provide clarity on this through revised wording or in the rationale box. We believe that a communication channel is a component of the communication system. Unless this is clear, it may lead to confusion during the necessary Protection System assessments.

2. Table 1 Footnote 13.3 – (Also, reference Section 5.8 of the NERC SPCS report) – we have two concerns with this footnote where a single DC system which "is not monitored or not reported for low voltage and open circuit is considered non-redundant." Firstly, it should be noted that in a single DC battery system, the RTU will likely also lose DC supply meaning a loss of DC supply alarm could not annunciate that specific condition to a control centre directly. Secondly, the use of the term "open circuit" is too broad. An open circuit in the battery system can be caused by many things, such as loose connections at the battery or any downstream DC breaker/fuse opening. We believe the intent of this footnote is to capture only the opening of the main protective device (breaker/fuse) after the DC system. In light of these 2 issues, we would like to suggest the following wording change to address these concerns:

13.3 A single DC supply associated with protection functions, and that single station DC supply is not monitored or not reported, either directly or indirectly, for both low voltage and for interruption of the station DC supply by the main protective device." We believe this wording along with appropriate rationale would help clarify this footnote.

3. Table 1 Footnote 13.4 - (Also, reference Section 5.5, Section 5.6, and Section 5.7 of the NERC SPCS report) - If the drafting team considers monitoring for commumication system and DC supply to satisfy redundant requirements, then why can't trip coil monitoring be considered as well?

Item #1 states a single relay, not a single protection package. Is our interpretation for item #1 that a package of (electromechanical) component relays (i.e. three relays in the single package) is redundant in accordance with TPL-001-5 correct? Since, within the sensitivity of the devices, a set of 3 phase and 1 ground relay detects any of the classic fault types (3PH, Ph-Ph, DLG, and SLG) with at least two (2) relays. We would like to provide an example with a transmission line that does not have two directional ground relays, but one directional distance relay (KD relay) per phase and one directional distance ground relay (IRD relay) for the SDT's review. With a single line to ground fault and the directional distance ground relay fails, the instant overcurrent relay will operate, but at a potentially different (e.g., slower) speed (depending on the fault current magnitude). In accordance with footnote 13, should the directional distance ground relay and the overcurrent relay be considered redundant, and hence not constitute a single point of failure per TPL-001-5? If the relays in the example are considered redundant, could we assume either relay to operate and hence do not need to consider them non-redundant components of a Protection System per footnote 13? Alternatively, if the relays in the example are considered non-redundant, do we need to test for operation of either of the two relays (i.e. both) per footnote 13?

Item #2 does not specifically state anything about the speed of protection, although the associated rationale statement states that the evaluation shall address all Protection Systems affected by the failed component and the increases (if any) of the total fault clearing time. Is our interpretation for item #2 that one high speed and one step distance will provide a correct operation, so it doesn't need to be tested under footnote 13? Is our interpretation for item #2 that while a single communication system applied over a single communication medium which is not monitored or not reported constitutes a non-redundant component of a Protection System, a monitored pilot channels, such as FSK, is to be considered a redundant communication system in accordance with footnote 13? Further, is our interpretation for item #2 that this extends to on-off carrier channels with check-back testing so that only those without check-back reporting are considered non-redundant in accordance with footnote 13?

It appears that the addition of “A single communications system, necessary for the correct operation of protective functions, which is not monitored or not reported” is beyond the scope of the SAR and the SPCS and SAMS recommendations in response to FERC Order No. 754. Please consider if this addition to footnote 13 is necessary.

Is our interpretation for item #3 that it is sufficient to monitor the battery and alarm if it is getting low correct in accordance with footnote 13? In other words, are we required to evaluate the failure of the battery, or is it sufficient to monitor for low battery voltage, while not knowing when it actually fails?

Could the SDT please provide further guidance in form of clarifying language or application guidance as related to item #4 in footnote 13? Is our interpretation related to item #4 that redundant relays tripping through a single wire to a single trip coil would constitute a non-redundant component of a Protection System? While item #4 does not seem to require dual trip coils, it seems to require dual wires. Does the last sentence provide a correct interpretation of a single control circuitry associated with protective functions through the trip coils of the circuit breakers or other interrupting devices per footnote 13?

Reference footnote 13, bullet 4: We recommend to replace the word “through” with “up to” to make the requirement clearer and less prone to different interpretations.

If the drafting team decided that the listed four items in Footnote 13 define single points of failure of Protection Systems, NPCC suggests revised language in order to provide clarity for both the Planners as well as the P&C SMEs who will be called upon to evaluate the Protection Systems. We suggest the wording in the standard be clarified either directly or through appropriate descriptions in the rationale boxes. We also note that the 4 items in the footnote seem to be a mix of truly redundant components or singular components whose health is monitored. True Protection System redundancy to avoid single point of failure does not depend solely on health monitoring to meet redundancy requirements. We note and reference a previous work by the NERC SPCS concerning protection system redundancy entitled Protection System Reliability – Redundancy of Protection System Elements” (November 2008) where much of the wording in Footnote 13 and the corresponding rationale was derived from.

Please consider the following comments and suggestions:

1. Table 1 Footnote 13.2 – (Also, reference Section 5.4 of NERC SPCS report) – Please clarify if the intent that a single monitored communication system necessary for correct operation of protection functions means that a single communication *channel* which is monitored meets the redundancy requirement. Quoting from the NERC SPCS report identifying redundant tele protection schemes:

Some acceptable communication schemes are:

• Two power line carrier systems coupled to multiple phases of the line.

• Two microwave systems and paths with multiple antennas on a common tower.

• Two fiber paths between terminals (two fibers in the same cable are not acceptable)

• Two separate communication systems of different technologies and equipment (e.g., fiber optic and digital microwave).

It would appear from the draft wording for this footnote that any singular communication channel, as long as it is monitored, does not need to be considered in the planning assessment. Please provide clarity on this through revised wording or in the rationale box. We believe that a communication channel is a component of the communication system. Unless this is clear, it may lead to confusion during the necessary Protection System assessments.

2. Table 1 Footnote 13.3 – (Also, reference Section 5.8 of the NERC SPCS report) – NPCC has two concerns with this footnote where a single DC system which "is not monitored or not reported for low voltage and open circuit is considered non-redundant." Firstly, it should be noted that in a single DC battery system, the RTU will likely also lose DC supply meaning a loss of DC supply alarm could not annunciate that specific condition to a control center directly. Secondly, the use of the term "open circuit" is too broad. An open circuit in the battery system can be caused by many things, such as loose connections at the battery or any downstream DC breaker/fuse opening. We believe the intent of this footnote is to capture only the opening of the main protective device (breaker/fuse) after the DC system. In light of these 2 issues, we would like to suggest the following wording change to address these concerns:

"13.3 A single DC supply associated with protection functions, and that single station DC supply is not monitored or not reported, *either directly or indirectly*, for both low voltage and *for interruption of the station DC supply by the main protective device."* We believe this wording along with appropriate rationale would help clarify this footnote.

3.Table 1 Footnote 13.4 - (Also, reference Section 5.5, Section 5.6, and Section 5.7 of the NERC SPCS report) - If the drafting team considers monitoring for communication system and DC supply to satisfy redundant requirements, then why can't trip coil monitoring be considered as well?

We would like to see further clarification under P5 and the new Extreme Events (2e through 2h) as to where the fault and the failure of the components of a Protection System occur. Is the intent of these new faults to have the fault and the failure of the component of the Protection System locally, remotely, or both?

Can this be added ("local failure of a non-redundant component of a Protection System", or "remote failure of a non-redundant component of a Protection System", or "local and remote failure (not simultaneously) of a non-redundant component of a Protection System") to the P5 and Extreme Events?

A fault locally along with a local failure of a component of a Protection System would be similar to NPCC's Criteria A-10 test, however, a fault locally with a remote failure of a component of a Protection System would be a scenario new to the industry, possibly leading many entities to discover scenarios where they have un-cleared faults, however this may not be apparent to entities to be studied unless it's clarified in the standard.

Clarification on communication-aided schemes is needed. The rational states that communication failures do need to be considered in the SPF analysis. Often, and general good utility practice is to provide separate communication paths for critical protection systems, such as redundant fiber on separate routes, fiber and microwave, diverse frequencies on the same microwave path, PLC on separate phases of a line, OPGW and PLC on a line, etc.   Other, less redundant communication configurations are also possible such as multiple individual channels in the same fiber or microwave frequency and path or two OPGW cables on the same structure.

- Is a communication configuration that uses this lower level of redundancy acceptable under the revised P5 and footnote 13?
- Would monitoring and reporting failures of such “less or non redundant” communication facilities make them acceptable?
- How about communication facilities that carry signals for RAS or other controls whose action may not be dependant on the physical telecommunication path?

If the answers to any of these questions are “yes,” that would seem to contradict the SPCS white paper from 2009, which included several examples, in the discussion on communication redundancy.   It may also provide a lower standard for communication compliance than for protective relay compliance. This would not appear to be a desirable reliability result.

Comment	

Duke Energy recommends the SDT consider that "*Non-redundant component*" be clarified to refer to "fault clearing initiating devices" leaving the wiring to the discretion of the results of the studies. (relays, carrier, battery, etc.) Duke Energy has concerns regarding the lack of information on what level of redundancy will be required. Based on the rationale provided, it appears that redundancy will not be required where cascading (result of a study) is not a concern, however, more clarity is needed regarding what redundancy would look like as it pertains to this standard. Where redundancy is required does this mean putting in a complete second system to meet compliance for item 4? *"4. A single control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices"?* Does separate circuits, mean separate in same panel or separate in separate panels. Does it mean separate cables in same conduit or separate cable in separate conduit, or could it mean separate conductor in same cable. Regarding redundancy of control circuits, does redundancy mean that separate trip coils are required in the breaker? More clarity is needed on this aspect to fully understand what compliance will look like. Also, regarding #2 in Footnote 13, where it says *"single communication system",* does this mean separate pairs in same cable, or does it mean fiber pair from two cables in two different paths? More clarity is needed on what the SDT's intent is for this language.

PG&E agrees that adding the components of a protection system to study provides clarity but the impact of this study is not known and more information is needed. The work required to respnd to the FERC ORDER 754 data request was significant and PG&E believes that this change may result in unduly burdensome activities without knowing what the full scope of non-redundant facilities are. Furthermore PG&E believes that the Transmission Owner may need to be added as an applicable entity to identify the facilities which do not meet the redundancy criteria specified here and assist in identifying the resulting outages and clearing times.

The SPP Standards Review Group suggests that on the rationale on page 23 of 33, there seems to be rationale missing, supporting communication- aided components of a protection system. The SPP Standards Review Group suggests that in footnote 13, clarify that this is a finite list, and add some punctuation to define the list. Additionally, clarify Statement 4, and provide an explanation. The SPP Standards Review Group suggests this would be more appropriately addressed in a PRC standard due to the protection scheme issues. The SPP Standards Review Group suggests that the drafting team add clarity to the guidance document to address Directional Comparison Blocking (DCB) protection and whether or not it meets the intent of redundancy and what is meant by monitoring the communication system.

The potential cost of this to improve our system would be phenomenal. Even though it is only limited to 3-phase faults, this would produce additional burden to the annual planning assessment. NERC 754 required us to do this with the understanding that if there was such a scenario, it would not be counted as a violation. Now they are adding this to a point that it would be a violation.

CenterPoint Energy disagrees with the further clarification. CenterPoint Energy recommends deleting item (b) in Footnote 13: "A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported." CenterPoint Energy's recommendation is based on the following:

•   The System Protection and Control Subcommittee (SPCS) and System Modeling and Analysis Subcommittee (SAMS), after performing an extensive analysis by their subject matter experts, did not recommend including communication systems in Footnote 13 (Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request, September 2015).
•   A communication system was not part of the Standards Authorization Request as one of the non-redundant components of a Protection System to consider for inclusion in Footnote 13.
•   Monitoring communications equipment of communication-aided protections schemes is extensively utilized. In addition, NERC Standard PRC-005, Transmission and Generation Protection System Maintenance and Testing, encourages monitoring of communication systems, to avoid frequent manual testing, for entities that have no monitoring or entities that do not yet have monitoring of one hundred percent of their applicable communications systems.
•   The September 2015 SPCS/SAMS assessment noted that a communication system failure will not prevent high-speed tripping (i.e., does not result in Delayed Fault Clearing) for certain protection system designs, such as a directional comparison blocking scheme (DCB), which is extensively utilized.
•   Including communication systems in Footnote 13 results is a compliance burden that does not provide commensurate reliability benefits.

CenterPoint Energy comments on the wording of the Rationale for Table 1 P5 Event and Footnote 13 are as follows:

•   The first sentence of the first paragraph states an entity must model a single point of failure of a non-redundant Protection System component "that may prevent correct operation of a Protection System…" CenterPoint Energy recommends replacing this phrase with: "that will result in Delayed Fault Clearing associated with a failure to trip." CenterPoint Energy recommends deleting the second sentence: "The evaluation shall address all Protection Systems affected by the failed component and the increases (if any) of the total fault clearing time."
•   In the second sentence of the fourth paragraph, CenterPoint Energy recommends adding that the SPCS/SAMS report also described a communication system as having a lower level of risk of failure to trip.
•   CenterPoint Energy recommends review of the fifth paragraph and Footnote 13d. The fifth paragraph states the team sought to limit the scope of protective relays to those used for "primary protection," not including "backup protection." However, the terms "primary" or "backup" protection are not used in Footnote 13 that uses the NERC term Protection System. Based on the NERC Glossary definition, a Protection System at a substation for an Element could include two, or more, protection schemes whether the schemes are called primary/backup, primary/secondary, or scheme 1/scheme2.
•   CenterPoint Energy concurs with the wording of Footnote 13 item (a) of "A single protective relay," which does not include language that it applies only to protective relays "which responds to electrical quantities." This allows the use, if appropriate, of a sudden pressure relay as redundant for transformer differential protection. Sudden pressure relays were addressed by the SPCS (Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities - SPCS Input for Standard Development in Response to FERC Order No. 758, December 2013)

The SRC offers the following comments regarding clarification of relay components of a Protection System:

1) Clarity needs to be added to “single relay” to exclude instances where a second relay performing a different function is also installed.

2) Clarity needs to be added to “single communication system” to specify the devices that need to clear a fault as opposed to devices that may result in overtrip.

3) Clarity should be added to allow for redundancy provided by devices responding to non-electrical quantities.

4) Clarity should be added for what constitutes “not monitored” or “not reported” in the instances of communication system and DC supply.

5) Item #4 is unclear if it is requiring two trip coils. This needs to be clarified.

6) Do the trip coils need to be monitored?

7) It is not clear on how trip coils are to be evaluated. An application guide to provide more detail on and explain the proposed footnotes would be helpful. 8) Wouldn't the single control circuitry just be a concern up to the point of initiating breaker failure (not to the trip coil). In other words, as long as breaker failure is initiated, then the event would be captured under P4. 9) The parenthetical that specifies the different relay types should not be deleted because the term "single protective relay" is not specific enough. 10) While the revised footnote is an improvement, clarifications are still needed to properly identify the redundancy requirements. We believe that minimum design requirements or a guideline should be included in the standard. That will allow the Planning Coordinators/Transmission Planners to have a consistent interpretation of the footnote 13. 11) There are situations when non BES elements are connected to BES buses (e.g. radial circuits supplying loads). The standard must clarify which protection systems failures needs to be studied since an uncleared close in fault on a non BES element connected to a BES bus has the same consequence as an uncleared close in fault on a BES element. 12) Do the protection systems installed on non BES elements connected to BES buses and protecting portions of the BES buses need to meet redundancy criteria?

The FERC Order 754 SPCS report specifically recommended adding the components from the definition of protection system. Within that definition, protective relays are described as "Protective relays which respond to electrical quantities". This is an important distinction which is missing from the proposed addition/revision to footnote 13.

The footnote is unclear and requires additional clarity. After review by the System Protection Engineering group, they have determined that the drafting team's attempt to provide clarity falls short of its intent. Additionally The inclusion of 3phase faults in the Extreme events stability runs will require a substantial incease in the amount of stability files that need to be created, constantly reviewed, and ran on a regualar basis. This will greatly increase the burden on the TP.

SNPD suggests replacing the entire footnote 13 with a simple statement "Fault followed by a failure of the Protection System resulting in delayed trip from local and remote substations." This objective would require an Entity to assess and validate potential event(s) within its Bulk Electric System. We also suggest the Drafting Team consider the loss of the station battery as an extreme event (Category P7) that causes no trip at the local station and the faulted event can only be cleared from remote trips (Delayed Fault Clearing.)

1. Tacoma Power does not agree that all parts of the Protection System should be treated identically with regards to single point failures. As identified the order 754 final report, some protection system components such as protective relays, auxiliary relays, and DC circuits downstream of the DC panel branch circuit protection have been documented as common causes of actual single point failures. The final report also identifies that AC inputs and the station DC supply pose much lower risk of failure to trip. The attached table shows an alternative set of contingencies that would implement a more risk-based approach to single point failures of each kind of component in the protection system.

2. Tacoma Power proposes P5 include the more common kinds of failures of the protection system that include 1) Protective relays which respond to electrical quantities; 2) A single communications system, necessary for correct operation of protective functions, which is not monitored; and 3) Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

3. New P8 and P9 contingencies for EHV facilities would address the remaining less likely to fail components of the protection system including (1) Voltage and current sensing devices providing inputs to protective relays, (2) Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply). Since these kinds of components are less likely to fail, allowing interruption of firm transmission service and nonconsequential load should be allowed for all voltage levels.

The 754 report found that only 0.7% of 100-199 kV buses had adverse system response from a single point of failure whereas 20% of EHV buses had adverse system response from a single point of failure. This disparity indicates efforts mitigating single component failures should be focused on the EHV system. The new P8 and P9 (i.e. the proposed d-h extreme events) should apply to just EHV elements. Creating new events P8 and P9 would clarify that Corrective Action Plans are required for these contingencies whereas extreme events do not require CAPs. 4. Tacoma Power supports reformatting of Table 1, as it is currently quite confusing. 5. There appears to be confusion as to whether to monitor protection circuits, the battery bank or the main DC breaker for open circuit. Trip coil monitoring does not provide any assurance the batteries are connected. Furthermore, there appears to be a lack of publicly available evidence that battery open circuit monitoring substantially lowers the risk of the protection system failing to trip. Dual batteries may be more appropriate for many EHV applications. 6. Battery monitoring system cost roughly the same amount as the set of batteries they monitor. Imposing additional costs for battery monitoring systems may lead to utilities replacing battery banks less often. 7. If the SDT continues to include monitoring as a viable option, these additional clarifications are need: (1) battery open circuit monitoring is required, (2) every breaker/fuse in the DC system must be monitored if it is a single point of failure, (3) a single trip coil is a single point of failure and is not mitigated by having trip coil monitoring unless there is independent breaker failure control circuitry, (4) low voltage monitoring threshold for battery voltage shall be coordinated with the battery design to give indication with at least 50% of battery capacity remaining, (5) auxiliary type relays for loss of DC may not be sufficient for low voltage monitoring of the battery, although they may be used for monitoring for loss of DC, and (6) non-battery-based DC systems require redundancy and should be addressed in a separate bullet under Footnote 13. 8. If monitoring of Protection System components is counted for purposes of TPL-001-5, is it the drafting team's intent that an entity would be obligated to maintain the alarming paths and monitoring systems under PRC-005-6 (Requirement R1, Part 1.2, and Table 2)? An entity should be allowed to consider monitoring for purposes of TPL-001-5 but treat the associated Protection System component(s) as unmonitored for purposes of PRC-005-6. 9. Additional clarification is requested on the demarcation between station DC supply and control circuitry for purposes of TPL-001-5. It is recommended that the main breaker of DC panels be considered part of the station DC supply.

SNPD agrees with simulating extreme events for the Near-Term Planning Assessment Study so we can learn from and understand the constraints of the BES and we can share results for situational awareness and work jointly with our PC/TP/TOP to develop short-term solutions. However, while it is feasible to study and develop an awareness of the BES for the Long-Range Planning Cases, SNPD suggests the Drafting Team not require a Corrective Action Plan(s) for the Long-Range Planning Cases, as it is not practical to require an Entity to develop a Long-Term Corrective Action Plan for extreme scenarios for the 5-year and beyond planning cases.

We conceptually disagree with *requiring* any mitigation for extreme events – this would be a deviation from the long-standing planning philosophy of assessing the risks and consequences to BES reliability for Category D contingencies (i.e. extreme events) and permitting the transmission planner to exercise its discretionary judgment to identify usage of any corrective action(s) to reduce system vulnerability to extreme events.

Comment	
We have three concerns with this addition in R4.6. First is that the appropriate location in the standard for determining what events require Corrective Action Plans is R2.7, not R4. The second concern is that no other extreme events currently mandate projects (CAPs) to address performance issues. FMPA can find no instance in which FERC ordered that assessments of failure of a component of a protection system with a three phase fault be required to be remedied with a CAP, and furthermore, we find no instance in the SPCS Order 754 report where this was stated either. By all accounts the explicit changes to Table 1 items 2e-2h and the changes to the P5 event should have addressed FERC's concerns and should have addressed the recommendations of SPCS in the Order 754 report. By including the new requirement R4.6, the drafting team is ostensibly concluding that any projects that are proposed to address 2e-2h will be inexpensive and "easy to fix". While that may be likely, it cannot be guaranteed. Throughought the standards and the standards development process, industry is routinely informed that standards are not mandating capital projects, but that is excactly what this requirement is doing. The third concern is that it will be difficult/complicated to demonstrate compliance with this requirement, for a number of reasons. First is that Cascading is nowhere near as cleanly defined and identified as "delayed clearing" is. Secondarily, if the goal of these simulations is now to find events that	

result in cascading, the table 1 criteria for identifying events that result in "delayed clearing" simply was not written with that goal in mind. It was written to look for events that have significant stability impacts/cause that cause disruptions within the power system. Delayed clearing does not equate to "cascading". Where this comes into play is in assessing R4.4 contingency lists, where the PC and TP exercise engineering judgment to select which events will be the most severe. Since the Table 1 criteria for 2e – 2h specifically require delayed clearing, the PC or TP may select events in different locations.

The SRC does do not agree with the addition of Requirement 4, Part 4.6. We believe this addition contradicts with the basic design, planning and operation criteria of the BES, and exceeds the overarching objectives of achieving an adequate level of reliability. The intent of assessing extreme events is to get a feel of how the system would perform under such conditions. Where possible, actions could be speculated or designed to mitigate the adverse impact, as already mandated in Part 4.5 of the existing TPL-001-4 standard. To go so far as requiring corrective action plans (CAP) to prevent or reduce the occurrence (such as by duplicating the non-redundant component) goes beyond the basic criteria for the design, planning and operation of the BES. Simply put, it goes beyond the adequate level of reliability. It might be fairly safe to say that quite a few entities will fail the extreme event testing under certain anticipated conditions for which the BES is not designed to withstand. Hence the existing requirement to evaluate possible actions to reduce the likelihood or mitigate the consequences of the event is appropriate, but to develop and implement CAPs for events (e) to (h) in Footnote 13 will incur in significant cost over and above what's needed to meet the basic criteria. This is philosophically, and in principle, a non-starter. We respectfully request the drafting team not to add this part. Note: ERCOT does not support this comment.

This change goes beyond the scope of the SAR. It essentially makes an Extreme Event equivalent to a Planning Event. Additionally, it is not clear whether the CAPs ever have to be built or if they just have to be on paper.

CenterPoint Energy disagrees with the proposed Requirement 4, Part 4.6, additions. CenterPoint Energy's disagreement is based on the following: • The SPCS and SAMS, after performing an extensive analysis by their subject matter experts, did not recommend requiring a CAP for a subset of Table 1 extreme events (Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request, September 2015). • Requiring a CAP for a subset of Table 1 extreme events (footnote 13, 2e-2h) was not part of the Standards Authorization Request. • Requiring documentation of a CAP for a specific, limited subset of Extreme Events results in a compliance burden that does not provide commensurate reliability benefits. If the analysis concludes there is Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h, an evaluation of possible actions designed to reduce the likelihood, or mitigate the consequences and adverse impacts of the event, should be conducted the same as with any other Extreme Event analysis that concludes there is Cascading.

The intent of 4.6 is already covered by the proposed changes to the P5 Category definition and reference to footnote 13. For instance, the EHV BES level does not allow for non-consequential load loss for a P5 contingency. In addition, the last sentence of 4.5 states "If the analysis concludes there is Cascading caused by the occurance of extreme events…an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences…shall be conducted." This statement effectively requires the development of alternatives. If there is a desire to strengthen 4.5 for events which lead to cascading related to non-redundant protection systems then it could be done in 4.5.

SMUD does not support the proposed changes; we do not agree with the addition of Requirement 4, Part 4.6. We believe this addition contradicts with the basic design, planning and operation criteria of the BES and exceeds the overarching objectives of achieving an adequate level of reliability. The concept of assessing extreme events is to obtain an understanding how the system would perform under such conditions. Where possible, actions could be speculated or designed to mitigate the adverse impact, as already mandated in Part 4.5 of the existing TPL-001-4 standard. Requiring corrective action plans (CAP) to prevent or reduce the occurrence (such as by duplicating the non-redundant component) goes beyond the basic criteria for the design, planning and operation of the BES. Any decision to assign resources in either prevention of an extreme event or the mitigation of impacts for an extreme event should be left to the discretion of the entities impacted rather than mandated by the standards	

Additionally, a corrective action plan implies a correction is necessary and could be interpreted as a mandatory action requiring full mitigation for impacts of the extreme events. Studies that evaluate the impact of these extreme events and identification of possible actions that would reduce the likelihood or mitigate the consequences of these event types, as appropriately covered in requirement R4.5.

The clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events – stability 2e-2h is a significant improvement to the proposed TPL-001-5. It addresses ALL the recommendations from SPCS and SAMS regarding single points of failure in protection systems in the report from Section 1600 Data Request following Order No. 754. This Order was issued directing NERC and Commission staff to initiate a	

process to identify any reliability issues for system performance following the loss of a single BES Element which appeared in the legacy TPL (version 0) standards. The conclusion from the report has rightfully and adequately addressed the Commission's concern. In general, the proposed TPL-001-5 removes the ambiguity from the legacy TPL standards for protection system failures.

However, the proposed new Requirement 4, Part 4.6 adding the Corrective Action Plan goes beyond the recommendation from the Section 1600 Data Request report for Order No. 754. In addition, the conclusion of the above report did not recommend setting the bar "higher" for performance than it is for current TPL-001-4 for extreme events in TPL-001-4 Part 4.5 nor did the SAR authorize the SDT

to do this. Any cascading due to an extreme event is already addressed in the Commission approved TPL-001-4 in Requirement 4, Part 4.5 wherein an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) is warranted. Besides, a cascading caused by the extreme event due to protection system single points of failure (Table 1 for P5 and extreme event – stability 2e-2h) is no different than a cascading due to any other extreme event (a cascading is a cascading; the end result is the same). And the Section 1600 Data Request report has very clearly put this in their conclusion in the second paragraph which is copied below verbatim:

"Additional emphasis in planning studies should be placed on assessment of three-phase faults involving protection system single points of failure. This concern (the study of protection system single points of failure) is appropriately addressed as an extreme event in TPL-001-4 Part 4.5. From TPL-001-4, Part 4.5: If the analysis concludes there is cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted."

The added clarification under Table 1 for Planning Event P5 and extreme event – stability 2e-2h along with footnote 13 sufficiently covers all the concerns that the Commission expressed in Order No. 754 as well as the conclusion and recommendation from the analysis for the same in the aforementioned report for the protection system single points of failure.

Besides, if Requirement 4, Part 4.6 goes into effect, there won't be any operational workaround on the cascading arising from such failures. The "only" Corrective Action Plan for these kinds of events is a new capital improvement project which will require a significant time and effort for coordination among PCs, TPs and the Facility owners and operators (TO/ TOP/ GO/ GOP). In addition, the installation/implementation of such Corrective Action Plans may cost the industry tens of billions of dollars with significant construction efforts spanning 10-20 years. This is a high-impact, low-frequency event risk that the industry, in order to identify and mitigate significant reliability risks, should develop action plans to reduce the likelihood or mitigate the consequences from such events keeping in mind their resources and budget which is already addressed in Requirement 4, Part 4.5.

Suggestion: Requirement 4, Part 4.6 is not needed.

Also, the rationale to include 3 phase faults with the failure a non redundant component of a Protection System is too onereous. This scenario with a SLG fault is onerous enough. The requirements in the Extreme Events Table 2e-h should be depicted in Table 1 Planning Events as a second Row of P5 with three-phase as the "fault-type" for several reasons: 1. Table 1 note (a) already covers "cascading" not being allowed – maybe eliminating the need for a new R4.6 altogether 2. Clearly shows this as a signitifcant "raising-the-bar" event requiring a CAP 3. Maintains the separation between Planning Events (requiring a CAP) and Extreme Events (requiring analysis and optional CAP An alternative to it being depicted as a second row of P5 with three-phase as the "fault type" could be to make a P8 for stability only.

This is a duplication of R4.5. This is not identified in FERC order 768, we find no clear need for this additional language. Furthermore extreme contingencies have not required formal corrective actions plans, this may result in unduly burdensome activities for rare and unlikely events.

(1) Requirement R4 focuses on the performance of Contingency analyses reflective of Table 1 by applicable entities. We believe the development of a Corrective Action Plan to address a potential Cascading event, in the Transmission Planning Horizon, should be included as a separate requirement. The Correction Action Plan should account for all viable solutions, including the delay of implementing corrective actions until specific operating conditions have been met, as such actions could require significant capital investment to implement. (2) The SDT should clarify the reference to “Cascading” as only those Elements which pertain to the BES definition. By its current application, the reference could include any Element, including non-BES Facilities.	

(3) Furthermore, while the inability to implement a Corrective Action Plan could directly and adversely affect the electrical state or capability of the BES, thus aligning it with the criteria of a Medium Violation Risk Factor, the development of the plan, as proposed, does not. We believe the failure to develop a Corrective Action Plan is administrative in nature and constitutes a Lower Violation Risk Factor in the Long-Term Planning Horizon.

(4) Based on our experience, we have seen a shift in the development of Reliability Standards towards referencing terms like “Element” and “Facility” to collectively align with the BES definition. We propose removing references to “System” to both requirement parts and reword Part 4.6.1 to “List deficiencies and the associated actions needed to prevent Facilities from Cascading.”

This subset of extreme events involves only 3Ø faults on various elements. In the presence of a Protection System SPF, this fault type may not be the most critical. The rational seems to anticipate that the revised criteria will be most applicable to legacy Protection Systems, since most newer PS are already designed using a higher level of redundancy. Many of the PS for these older schemes use single phase electromechanical or solid state relays. For such PS, a single relay failure would often not impact the ability to detect and clear a 3Ø fault, because two phase relays would still detect the fault and intiate clearing in the normally expected time *as though no relay failure had occurred*. The SPCS/SAMS report briefly alludes to this condition, but does not address an important System implication. A SLG fault on the same phase as the failed relay would not be detected within the primary protection zone and would result in delayed clearing. Of course, the number (System risk exposure) of SLG faults is much higher than for 3Ø faults. In most cases the same facilities are removed from service whether the delayed fault clearing results from a SLG or 3Ø fault. So, while it may initially sound counter intuitive, the more numerous SLG fault may actually have worse System impact than the 3Ø fault case with SPF.

- Does the drafting team interpret such SLG faults with Protection System failure as P5 (not extreme) events?
- If not, does it promote System reliability to not study the SLG fault case?

- If so, should another item be added to the list? The idea for such an item might read something like: If the non-redundant PS is implemented including single phase or ground relays, the e-h Element faults must also be studied for SLG faults with delayed fault clearing.

NVE would also like to suggest rewording Section 2 of the Stability portion of the Extreme Events table to help reduce wording,

2. Local or wide area events affecting the Transmission System such as:

- 3 phase fault on on any of the following equipment with stuck breaker resulting in Delayed Fault Clearing:

  - Generator

  - Transmission circuit

  - Transformer

  - Bus section

- 3 phase fault on any of the following equipment with failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing:

  - Generator

  - Transmission circuit

  - Transformer

  - Bus section

The proposed requirement R4.6 represents a major shift with regard to extreme events. The current TPL-001-4 requires that extreme events be studied, but there are no performance requirement for these extreme event Contingencies, and these extreme event assessments do not result in Corrective Action Plans (CAP). According to the proposed set of requirements, if extreme events result in Cascading, a CAP must be developed that would prevent those extreme events from resulting in Cascading. Today, extreme events do not drive the development of CAPs; if this requirement as written is approved, extreme events will drive the development of CAPs. Peak's major concern with this requirement is any implied expectation for extreme events to be included and protected against in operations (including outage coordination assessments, OPAs, and RTAs). Such an expectation would have devastating consequences (economic consequences and reliability consequences) for operations. Given the implied potential for such operational expectations, Peak disagrees with the proposed requirement. Example. Let's say that a Planning Assessment includes a few planned outages and that the Planning Assessment indicates that an extreme Contingency results in Cascading. If the outage weren't in place, the extreme Contingency would not result in Cascading. The TP isn't going to build anything to address that Cascading, because it's a temporary condition due to the outage. So the TP creates a CAP which is an Operating Plan to "fix" it. Fast forward to operations. Is it presumed that this extreme Contingency is now credible for operations and that the system needs to be operated in a manner that prevents the extreme Contingency from resulting in Cascading? Peak is VERY reluctant to endorse any kind of planning standard that in any way can be perceived to dictate to operations which Contingencies (beyond single Contingencies) must be protected against in operations…ESPECIALLY extreme event Contingencies. This approach removes the ability of the RC and TOPs within the RC Area to operate the system to manage risk when it comes to deciding which Contingencies beyond single P1 Contingencies need to be protected against. Peak believes that Planning Assessment of extreme event Contingencies and the resulting development of an associated CAP should in no way imply that those extreme event Contingencies need to be protected against in operations.

Comment	

Traditionally the intent of "extreme events" or "extreme contingencies" was to create awareness of the impacts of the studied contingencies, but not establish design requirements. Therefore, we recommend moving Table 1 Extreme Events Stability elements 2e through 2h from the Extreme Events table to Table 1 Planning Events, under a new Category P8, with the following attributes:

Category: P8 Multiple Contingency

Initial Condition: Normal System

Event: 2e through 2h

Fault Type: 3 phase

BES Level: HV, EHV

Interruption of Firm Transmission Service Allowed: Yes

Non-Consequential Load Loss Allowed: Yes

With this change, Requirement R4.6 should be revised as follows: "If the analysis concludes there is Cascading caused by the occurrence of Table 1 planning events P8, a Corrective Action Plan shall be developed…."

From our perspective, requiring the development of corrective action plans to include redundant relaying for extreme events is inconsistent compared with the existing TPL-001-4 requirements. Corrective action plans should include upgrades to meet planned events and local transmission planning criteria, but not for extreme events that have a very low probability of occurrence. If NERC/FERC wants redundant system protection systems to address these extreme events, then these requirements would be better suited to a PRC standard, and not a TPL standard. Transmission Planners should not be burdened with identifying which circuits are critical for which season or system condition so that protection engineers must install redundant system protection systems, which may only be needed for limited and specific system conditions.

We believe that further clarification is needed on Stability item 2f from Table 1 – Extreme Events. We believe that the terms "close-in" should be added to item 2f, so that it reads "3-phase close-in fault on Transmission circuit with failure of a non-redundant component of a Protection System resulting in Delayed Fault Clearing". We believe this change would reduce the number of scenarios that would need to be investigated from a stability perspective. Further, FERC Order 754 study only looked at close-in line and bus faults with remote clearing. For end of line 3-phase faults, fault detection is unlikely with a failure of a non-redundant System Protection Component due to in-feed effect. Therefore, it may not be possible to perform a reasonably valid stability study with this indeterminate state. If so, we believe that corrective action plans may be burdensome to complete. Given the low probability of a battery failure concurrent with a 3-phase end of line fault, we believe that inclusion of such events in the basic planning requirements is inconsistent.

Comment

A 3-ph fault is a very low probability event and should be mitigated through operating plans if the contingency shows that it results in cascading just like the other extreme events. PacifiCorp agrees that a list of reliability issues for the extreme events (2e-2h) should be developed such that operating plans can be developed, but requiring system upgrades as part of a corrective action plan is a significant burden on utilities without added benefit over an operating plan. Hence PacifiCorp recommends the drafting team remove the requirement of having a corrective action plan for such a rare event.

Requirement 4.5 of the TPL-001-4 standard has specified for the TPs/PCs "If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted". There is no justification given for why these particular extreme events should have more stringent requirements than other extreme events. A Corrective Action Plan (CAP) for extreme events should not be necessary, can be costly, and may not produce much benefit because of the low frequency of these type of events from happening. Suggestion: The addition of requirement 4.6 is not needed.

ATC does not agree with requiring the development of Corrective Action Plans (CAPs) for extreme stability 2e-2h events, or any other extreme events. We believe that the distinction between developing CAPs for “planning events” and not for “extreme events” is to recognize that the probability of extreme events is too low and the **cost to benefit ratio is too high to require the development of CAPs.** Part 4.5 already requires the evaluation of possible actions to reduce the likelihood or mitigate the consequences for all extreme stability events, including extreme stability 2e-2h events if there is Cascading. In addition, Part 3.5 also requires the evaluation of possible actions to reduce the likelihood or mitigate the consequences for extreme steady state events and there is no proposal for a Part 3.6 to require CAPs for any subset of steady state extreme events. (1) Is the intent of these CAPs to understand the scope of resolving the impact of the Extreme Events or to spend capital to resolve the issues?

Comment	
As stated in question 3, NIPSCO believes the addition of these components will involve most BES facilities. This will create more extreme type contingencies involving loss of a complete substation. Requiring a CAP on an extreme contingency on the amount of BES substations involved will lead to unreasonable mitigation costs. NIPSCO believes the requirement for all extreme events should suffice and the addition of proposed Requirement 4, Part 4.6 is unnecessary.	

If the intention of the SDT was to require a plan of action, with no time limit on acting on these plans, as Part 4.6 reads, then again, the current requirement for all extreme events should suffice.

As stated in response to Question 3 and repeated for emphasis, IEEE recommended practices are used in designing typical generator protection schemes. Prevailing protection schemes (based on IEEE Standards) for a majority of generators that are in service may not have completely redundant protection schemes as clarified by proposed footnote 13. It may not be practical for GO/GOP to implement a completely redundant protection scheme. For example, it may not be physically possible to install additional CTs on the generators or redundant battery systems. The Standard Drafting Team should develop an application guideline with appropriate figures to clarify the Standard Drafting Team's goal with this clarification. Refer to Figure 1.1 of NERC Technical Reference Document , "Power Plant and Transmission System Protection Coordination (http://www.nerc.com/docs/pc/spctf/Gen%20Prot%20Coord%20Rev1%20Final%2007-30-2010.pdf) Also, GO/GOP may not be able to implement corrective action schemes identified by the TP.

The concern is that the method the drafting team chose to implement the language seems out of order with the technical nature and system planning intent of Extreme Event contingency analysis. A better solution might be to create a new contingency category (e.g., P8) for 3 phase faults coinciding with protection system failures and also add the corresponding requirement under R2 where failure to meet the performance thresholds from R6 require a Corrective Action Plan. This will align with other TPL contingency analysis and also allow for Planning Coordinators to define more tailored mitigation requirements for its Planning Coordinator area. Additionally, putting the Corrective Action Plan requirement under R2 aligns with other Table 1 performance violations.

Comment	
Although PGE agrees that these single points of failure should be studied and identified, PGE does not agree with the requirement to develop a Corrective Action Plan. Corrective Action Plans are associated with capital improvements to add redundancy to the system. Adding redundancy to the system does not eliminate the possibility of an event, it only reduces the likelihood of the event. PGE recommends that utilities be given latitude to determine acceptable risk tolerances for events based on the likelihood of an event occurring and the consequence of that event. For example, it may be more likely for two old and unmaintained batteries to fail when called upon to act than one new and tested battery. The first case meets the requirement of the standard, while not providing system resiliency while the second would not meet the standard but could be a more economical and effective solution. The addition of a second battery to an existing substation could require rewiring or replacing existing relays or control buildings, replacing existing single trip coil breakers, and new trench systems. The cost of adding a second battery could be very high compared to alternative of assessing and managing the health of an existing battery to reduce the likelihood of failure. PGE recommends that the TPL standard offer performance criteria requirements in place of design requirements such as duel battery systems via Corrective Action Plans. The inclusion of Footnote 13.2 *A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported* may have unintended consequences. If a utility has implemented transfer trip to improve coordination, but not because transfer trip is required for system stability, a utility might elect to disable transfer trip rather than incur the addition costs of demonstrating compliance with this requirement. As an alternative, it may be more beneficial to require that the critical clearing time for all facilities be studied, and entities are required to report facilities with critical clearing times greater than that of the backup protection where there is a non-redundant communication path, and to develop Corrective Action Plans.

Comment	

The additions which require a Corrective Action Plan for the subset of Table 1 extreme events (footnote 13, 2e-2h) are beyond what is stated in the conclusion of the SPCS and SAMS “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request” report. This report recommended the following:

Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System13 that produce the more severe system impacts. For example, add a new second sentence that reads “[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2.”

Corrective Action Plans for low probability extreme events should not be required. However, it is reasonable that if Cascading is caused by the occurrence of an extreme event, an evaluation of possible actions designed to reduce the likelihood be conducted, as is currently stated in TPL-001-4 for extreme events (R4.5). Based on the conlusion of the above mentioned SPCS and SAMS report, it is understood that the intent should be to clarify that **both** three-phase faults with stuck breaker **and** failure of a non-redundant component of a Protection System13 resulting in Delayed Fault Clearing shall be considered as part of those extreme events in Table 1 that are expected to produce more severe System impacts in accordance with the existing language of TPL-001-4 R4.5. In other words, clarify that the “or” in Table 1 – Extreme Stability Events should not be interpreted as you only need to consider either stuck breaker or relay failure in R4.5. This is accomplished by simply breaking these events apart in Table 1 as shown below (and as in the current TPL-001-5 draft):

1. Local or wide area events affecting the Transmission System such as:

    i. 3Ø fault on generator with stuck breaker10 resulting in Delayed Fault Clearing.

    ii. 3Ø fault on Transmission circuit with stuck breaker10 resulting in Delayed Fault Clearing.

    iii. 3Ø fault on transformer with stuck breaker10 resulting in Delayed Fault Clearing.

    iv. 3Ø fault on bus section with stuck breaker10 resulting in Delayed Fault Clearing.

    v. 3Ø fault on generator with failure of a non-redundant component of a Protection System13 resulting in Delayed Fault Clearing.

    vi. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System13 resulting in Delayed Fault Clearing.

    vii. 3Ø fault on transformer with failure of a non-redundant component of a Protection System13 resulting in Delayed Fault Clearing.

    viii. 3Ø fault on bus section with failure of a non-redundant comoponent of a Protection System13 resulting in Delayed Fault Clearing.

    ix. 3Ø internal breaker fault.

    x. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

To further emphasize this point, refer to the alternatives for addressing reliability risks associated with single points of failure outlined in Charper 2 of the SPCS and SAMS report: · *Place additional emphasis on assessment of a three-phase fault and protection system failure* o *Provideds assurance that areas where a three-phase fault accompanied by a single point of failure that will cause an adverse impact are identified and evaluated* · *Elevate to a planning event with its own system performance criteria* o *Probability of three-phase fault with a protection system failure is low enough that it does not warrant a planning event* · *Keep as an extreme event with no change (other than footnote 13)* o *Does not provide assurance a three-phase fault with protection system failure is studied in planning assessments* From the above language describing the considered alternatives, it can be ascertained that the concern is ensuring that the language in the standard be updated to assure three-phase faults with protection system failure are studied in planning assessments, not that a "subset of Table 1 Extreme Events" be created that are treated differently than other Extreme Events by elevating them to requiring Corrective Action Plans because "the probability of three-phase faults with a protection system failure is low enough that it does not warrant a planning event". Furthermore, there is no technical justification to elevate a three-phase fault with failure of a non-redundant component of a Protection System events above three-phase fault with stuck breaker events. Although WAPA strongly disagrees with requiring a Corrective Action Plan for this "subset of Table 1 extreme events", if this requirement is carried forward WAPA recommends creating a separate P8 Event for these three-phase failure of a non-redundant component of a Protection System events because it makes Table 1 clearer to read, understand and differentiate between what is required of these events compared to other Extreme Events. **(see uploaded file Q/A #4)**

Since a Corrective Action Plan is not required, there is no need to create one. Corrective Action Plans would “gold plate” the system for very unlikely events.

We agree that an evaluation of a list of system deficiencies and associated actions needed to prevent the system from cascading for extreme events 2e-2h should be required; however, we disagree that TPL-001-5 should further require implementation of Corrective Action Plans to mitigate these extreme events. Instead, Transmission Planners and Planning Coordinators should be required to consider implementing actions – recognizing cost and other factors – to reduce the likelihood or completely avoid the consequences of these extreme events.

The additions which require a Corrective Action Plan for the subset of Table 1 extreme events (footnote 13, 2e-2h) are beyond what is stated in the conclusion of the SPCS and SAMS "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request" report. This report recommended the following:

Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

Corrective Action Plans for low probability extreme events should not be required. However, it is reasonable that if Cascading is caused by the occurrence of an extreme event, an evaluation of possible actions designed to reduce the likelihood be conducted, as is currently stated in TPL-001-4 for extreme events (R4.5). Based on the conlusion of the above mentioned SPCS and SAMS report, it is understood that the intent should be to clarify that **both** three-phase faults with stuck breaker **and** failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing shall be considered as part of those extreme events in Table 1 that are expected to produce more severe System impacts in accordance with the existing language of TPL-001-4 R4.5. In other words, clarify that the "or" in Table 1 – Extreme Stability Events should not be interpreted as you only need to consider either stuck breaker or relay failure in R4.5. This is accomplished by simply breaking these events apart in Table 1 as shown below (and as in the current TPL-001-5 draft):

2. Local or wide area events affecting the Transmission System such as:
   a. 3Ø fault on generator with stuck breaker[10] resulting in Delayed Fault Clearing.
   b. 3Ø fault on Transmission circuit with stuck breaker[10] resulting in Delayed Fault Clearing.
   c. 3Ø fault on transformer with stuck breaker[10] resulting in Delayed Fault Clearing.
   d. 3Ø fault on bus section with stuck breaker[10] resulting in Delayed Fault Clearing.
   e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   h. 3Ø fault on bus section with failure of a non-redundant comoponent of a Protection System[13] resulting in Delayed Fault Clearing.
   i. 3Ø internal breaker fault.
   j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

To further emphasize this point, refer to the alternatives for addressing reliability risks associated with single points of failure outlined in Charper 2 of the SPCS and SAMS report:

- *Place additional emphasis on assessment of a three-phase fault and protection system failure*
  - *Provideds assurance that areas where a three-phase fault accompanied by a single point of failure that will cause an adverse impact are identified and evaluated*
- *Elevate to a planning event with its own system performance criteria*
  - *Probability of three-phase fault with a protection system failure is low enough that it does not warrant a planning event*

- *Keep as an extreme event with no change (other than footnote 13)*
    - *Does not provide assurance a three-phase fault with protection system failure is studied in planning assessments*

From the above language describing the considered alternatives, it can be ascertained that the concern is ensuring that the language in the standard be updated to assure three-phase faults with protection system failure are studied in planning assessments, not that a “subset of Table 1 Extreme Events” be created that are treated differently than other Extreme Events by elevating them to requiring Corrective Action Plans because “the probability of three-phase faults with a protection system failure is low enough that it does not warrant a planning event”. Furthermore, there is no technical justification to elevate a three-phase fault with failure of a non-redundant component of a Protection System events above three-phase fault with stuck breaker events.

Although Corn Belt strongly disagrees with requiring a Corrective Action Plan for this “subset of Table 1 extreme events”, if this requirement is carried forward Corn Belt recommends creating a separate P8 Event for these three-phase failure of a non-redundant component of a Protection System events because it makes Table 1 clearer to read, understand and differentiate between what is required of these events compared to other Extreme Events.

The clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events – stability 2e-2h is a significant improvement to the proposed TPL-001-5. It addresses ALL the recommendations from SPCS and SAMS regarding single points of failure in protection systems in the report from Section 1600 Data Request following Order No. 754. This Order was issued directing NERC and Commission staff to initiate a process to identify any reliability issues for system performance following the loss of a single BES Element which appeared in the legacy TPL (version 0) standards. The conclusion from the report has rightfully and adequately addressed the Commission’s concern. In general, the proposed TPL-001-5 removes the ambiguity from the legacy TPL standards for protection system failures.

However, the proposed new Requirement 4, Part 4.6 adding the Corrective Action Plan goes beyond the recommendation from the Section 1600 Data Request report for Order No. 754. In addition, the conclusion of the above report did not recommend setting the bar “higher” for performance than it is for current TPL-001-4 for extreme events in TPL-001-4 Part 4.5 nor did the SAR authorize the SDT to do this. Any cascading due to an extreme event is already addressed in the Commission approved TPL-001-4 in Requirement 4, Part 4.5 wherein an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) is warranted. Besides, a cascading caused by the extreme event due to protection system single points of failure (Table 1 for P5 and extreme event – stability 2e-2h) is no different than a cascading due to any other extreme event (a cascading is a cascading; the end result is the same). And the Section 1600 Data Request report has very clearly put this in their conclusion in the second paragraph which is copied below verbatim:

"Additional emphasis in planning studies should be placed on assessment of three-phase faults involving protection system single points of failure. This concern (the study of protection system single points of failure) is appropriately addressed as an extreme event in TPL-001-4 Part 4.5. From TPL-001-4, Part 4.5: If the analysis concludes there is cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted."

The added clarification under Table 1 for Planning Event P5 and extreme event – stability 2e-2h along with footnote 13 sufficiently covers all the concerns that the Commission expressed in Order No. 754 as well as the conclusion and recommendation from the analysis for the same in the aforementioned report for the protection system single points of failure.

Besides, if Requirement 4, Part 4.6 goes into effect, there won't be any operational workaround on the cascading arising from such failures. The "only" Corrective Action Plan for these kinds of events is a new capital improvement project which will require a significant time and effort for coordination among PCs, TPs and the Facility owners and operators (TO/ TOP/ GO/ GOP). In addition, the installation/implementation of such Corrective Action Plans may cost the industry tens of billions of dollars with significant construction efforts spanning 10-20 years. This is a high-impact, low-frequency event risk that the industry, in order to identify and mitigate significant reliability risks, should develop action plans to reduce the likelihood or mitigate the consequences from such events keeping in mind their resources and budget which is already addressed in Requirement 4, Part 4.5.

Suggestion: Requirement 4, Part 4.6 is not needed.

TVA believes the occurence of a three-phase fault including a protection system failure would have an extremely low probability of occurring. As such, requiring implementation of a corrective action plan to fix these extremely rare events would cause a large and unnecessary financial burden with little benefit to our system reliability.

BPA believes that past performance can be a good indicator of future performance. These types of outages have not been an issue in the past. BPA believes that it is not economically justifiable to require corrective action plans for low probability extreme events like these. Instead, BPA believes an effort to minimize the likelihood of cascading should be considered, if studies indicate there is the potential for cascading on critical parts of the system.

Similar to our response to Q3, AEP believes that pursuing Corrective Action Plans as part of R4, Part 4.6 goes beyond the scope of the current SAR. Once again, we believe such an inclusion should not be considered until the SAR has been appropriately revised, and industry afforded opportunity to provide comment on the suggested change. As to the concept itself, AEP does not agree that Correction Action Plans would be justified or necessary in every case. Considerations such as the nature and/or extent of any potential cascading should be a factor in determining whether or not a CAP is necessary, but as currently written, the obligation does not allow such engineering judgment.

SDG&E is not against trying to simulate the extreme contingency events listed in Table 1, 2e-2h, but simulations of extreme events often end with a simulation failure. TPL-001 is a mandatory requirement and this makes section 4.6 binding on the TP/PC. If a simulation fails, the TP/PC will have no choice but to create a Corrective Action Plan. Regardless of cascading.

There are concerns with requiring the development of Corrective Action Plans (CAPs) for extreme stability 2e-2h events, or any other extreme events. The distinction between developing CAPs for “planning events” and not for “extreme events” is to recognize that the probability of extreme events is too low and the cost to benefit ratio is too high to require the development of CAPs. Part 4.5 already requires the evaluation of possible actions to reduce the likelihood or mitigate the consequences for all extreme stability events, including extreme stability 2e-2h events if there is Cascading. In addition, Part 3.5 also requires the evaluation of possible actions to reduce the likelihood or mitigate the consequences for extreme steady state events and there is no proposal for a Part 3.6 to require CAPs for any subset of steady state extreme events. Is the intent of these CAPs to understand the scope of resolving the impact of the Extreme Events or to spend capital to resolve the issues? The NSRF suggests the SDT mine the Event Analysis data to determine how many dynamic stability events occurred due to the lack of a redundant protection system component covered under Footnote 13. The benefit is the reduction and severity of events, while the costs could be significant.

Traditionally the intent of “extreme events” or “extreme contingencies” was to create awareness of the impacts of the studied contingencies, but not establish design requiements. Therefore we recommend moving Table 1 Extreme Events Stability elements 2e through 2h from the Extreme Events table to Table 1 Planning Events, under a new Category P8, with the following attributes: Category: P8 Multiple Contingency Initial Condition: Normal System Event: 2e through 2h Fault Type: 3 phase BES Level: HV, EHV Interruption of Firm Transmission Service Allowed: Yes Non-Consequential Load Loss Allowed: Yes With this change, Requirement R4.6 should be revised as follows: “If the analysis concludes there is Cascading caused by the occurrence of **Table 1 planning events P8**, a Corrective Action Plan shall be developed…..”

Comment	
We do not agree with the addition of Requirement 4, Part 4.6. We believe this addition contradicts with the basic design, planning and operation criteria of the BES, and exceeds the overarching objectives of achieving an adequate level of reliability. The intent of assessing extreme events is to get a feel of how the system would perform under such conditions. Where possible, actions could be speculated or designed to mitigate the adverse impact, as already mandated in Part 4.5 of the existing TPL-001-4 standard. To go so far as requiring corrective action plans (CAP) to prevent or reduce the occurrence (such as by duplicating the non-redundant component) goes beyond the basic criteria for the design, planning and operation of the BES. Simply put, it goes beyond the adequate level of reliability. It might be fairly safe to say that quite a few entities will fail the extreme event testing under certain anticipated conditions for which the BES is not designed to withstand. Hence the existing requirement to evaluate possible actions to reduce the likelihood or mitigate the consequences of the event is appropriate, but to develop and implement CAPs for events (e) to (h) in	

Footnote 13 will incur in significant cost over and above what's needed to meet the basic criteria. This is philosophically, and in principle, a non-starter. We respectfully request the drafting team not to add this part. However, if the SDT wants to proceed with its proposed approach the following needs to be clarified: This requirement creates ambiguity in studying events. Though the standard requires studying three phase faults, there is no indication about the fault location which influences whether cascading will occur. Generally in the planning studies the faults are applied on the buses since they produce more severe system impacts. When the "component failure of a Protection System" is considered and studied, a bus fault or a close in fault may still be cleared remotely by the back up protections (remote 21 timed, 51, 51N etc.) and Cascading may not occur. When the fault location is moved along the circuits there may be locations, where the fault will remain uncleared, since the remote back up protection systems may not be able to detect the fault, creating conditions for cascading to occur. Planning Engineers are familiar with the protection systems' behavior when they operate as expected. In case the intent of the standard is to study faults at any location (e.g. away from a substation bus) on circuits protected by a nonredundant protection system , then the planning assessment will require additional info from protection system owners (e.g. the performance of the remote backup distance elements required to clear faults while the local protection systems experience single component failure; this is not presently documented for all fault locations that potentially can cause cascading). If this is the intent of the requirement, then the standard should include specific requirements for protection system owners to provide necessary data to the planners.

KCP&L agrees with the content but sees an opportunity to improve clarity by making the specific extreme event a separate category of contingency. A Corrective Action Plan (CAP) is required only in the case of the described specific extreme event identified in the question as "a subset of Table 1 extreme events." Making a separate contingency category sets it apart and highlights the CAP requirement. We believe, in this instance, there is value in emphasizing the required response of completing a CAP in the event of the described extreme event.

While less probable than single-phase-to-ground faults, three-phase faults are single events and single-phase-to-ground faults will often evolve into three-phase faults under severe delayed clearing scenarios such as a P5 contingency. Therefore, to the extent these extreme events cause cascading, it may be prudent to require a corrective action plan. However, consideration should be given to handling this as a Table 1 P8 contingency where the performance requirement is simply no cascading or loss of stability. This is a cleaner way to address this issue because it does not introduce additional performance requirements for the extreme event category.

5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))	
Leonard Kula - Independent Electricity System Operator - 2	
Answer	No
Document Name	
Comment	
Due to referencing RC in the proposed requirement 1.1.2, it should be added as an applicable entity if the proposal is adopted, however, the RC should not have any involvement in the near-term planning timeframe. Also, TO needs to be added as an applicable entity if the three phase fault is moved along the circuit to determine the location for cascading as explained in Q4 above.

Robert Ganley - Long Island Power Authority - 1	
Answer	No
Document Name	
Comment	
As mentioned in our comments to Question #1, , we would suggest the SDT investigate the possibility of taking a step back and altering proposed requirement 1.1.2 to make it applicable to a TOP and also a TP. The TOP may be in the best position to be aware of known / planned outages in the near term planning horizon, and to be able to identify such outages to the TP. As stated in the rationale, the goal is not to consider hypothetical outages. The TOP may be in the best position to identify known / planned outages, prioritize them in terms of reliability impact, and then them provide to the TP for analysis in the annual near term planning horizon planning assessment. If the TOP is not the right applicable entity to share this requirement with the TP , then perhaps the RC is the correct entity.	

Consistent with this suggestion, we would note that the ERO Enterprise-Endorsed Implementation Guidance for TPL-001-4 mentions, for Req #1.1.2, the practice of obtaining “known outages information from applicable (in its area or in an adjacent area) Reliability Coordinators (RCs), Generator Operators (GOPs), or Transmission Operators (TOPs).”

For meeting the compliance for Requirement R1 – part 1.1 – subpart 1.1.2 and for Requirement R2 – part 2.1 – subpart 2.1.3, the cooperation of the RC is required by PCs and TPs. But RC is NOT under compliance requirement for this action since the standard is NOT applicable to them. Hence, inaction from RC can expose PCs and TPs to possible violation with these sub-requirements. Instead **IRO-017 Outage Coordination** standard is a better venue to address FERC's concern from Paragraph 40 and **TPL-001** standard should be maintained solely as a *true* Transmission Planning Standard. **Suggestion**: Address this in a future revision of IRO-017.

The standard should not involve the RC. However, the standard should direct the PC or TP to consult with the TO to determine whether or not specific facilities are applicable to P5 contingencies based on single points of failure and how the remote backup protection would respond for a P5 contingency in terms of sequence of events, clearing times, and additional facilities tripped, and reclosing. Perhaps the TO should be an applicable entity responsible for	

defining and providing the P5 contingency definitions to the PC and TP. Protection system are complex and often vary across a system, so protection engineers should be involved in defining the details of P5 contingencies.

Depending on how R1, Part 1.1.2 is revised, the RC may have an obligation to provide consultation to the TP/PC, or otherwise the TP/PC can be assessed non-compliant if the RC does not respond to the TP/PC’s requests. Therefore the RC should be a responsible entity.

Colby Bellville - Duke Energy - 1,3,5,6 - FRCC,SERC,RF, Group Name Duke Energy	
Answer	No
Document Name	
Comment	
Duke Energy requests further clarification from the SDT on the rationale to leave the RC out of the applicability of this standard. If TPL-001-5 R1.1.2 remains as is in the proposed standard, then the RC must appear in the Applicability portion of the standard. The RC has an explicit role to determine what outages must be studied, not a role as a consultant. Outages are not singular isolated events. Outages occur in combinations and under varying system conditions. The RC, not the transmission planner, has the more appropriate background knowledge and skill set to make the best determination on what to study. Neither the proposed TPL-001-5, nor the existing IRO-017 make clear the RC has lead responsibility that it should for ensuring proper evaluation and coordination of outages has been performed. We understand that it is inferred that IRO-017 covers this action from the RC. Even there the responsibility is only on the PC/TP to jointly develop solutions with its RC for identified issues or conflicts. No explicit language in IRO-017 exists that requires the RC to provide the outage that must be studied to the PC/TP. We reiterate that actions requiring operational personel to perform work should rest in an operational standard.

Due to the emphasis on planned maintenance outages it is important that the parties which will provide the known outage information to the Planning Coordinator and Transmission Planner be assigned to the Reliability Standard to ensure that information is provided in a timely manner. This may include the Reliability Coordinator, Tranmission Operator, Transmission Owner, Generator Owner or a combination of those functional entities. Additionally the Transmission Owner should be included for purposes of single point of failure due to non-redundant Protection System elements. Finally, Distribution Provider should be added anywhere Load Serving Entity is mentioned.

The proposed “consultation” approach, as currently drafted, raises a number of issues. Most critically, the proposed standard imposes no compliance obligations on the RC, but permits the TP and PC to exempt certain projects by “consulting” with the RC, which implies action by the RC. As such, a PC or TP could potentially omit certain P1 contingencies from their annual Planning Assessments and then provide that information to the RC. The TP and PC do not have to obtain the RC’s consent or approval to the proposed omissions. Thus, merely providing this information arguably constitutes a “consultation” under the Standard. The RC in turn is under no affirmative obligation to act on that request. As a result, P1 contingencies could not be modeled and may not have been fully considered by the RC, but the resulting Planning Assessment would still comply with the standard. Given this fact, the proposed extension of a “consultation” process to all planned outages raises a number of issues and is over broad. Texas RE suggests the SDT clarify what constitutes a valid consultation and should at a minimum limit the application of a “consultation” exemption to planned outages with a duration of less than six months.

Shannon Mickens - Southwest Power Pool, Inc. (RTO) - 2 - SPP RE, Group Name SPP Standards Review Group

Answer	No
Document Name	
Comment	

The SPP Standards Review Group proposes that a standard applicable to the Reliability Coordinator (RC) address RC requirements should be considered. Potentially, it could be added to NERC Stanadard IRO-017.

The SPP Standards Review Group suggests that the Transmission Owners (TOs) and Generator Owners (GOs) should be added to the applicability section of the standard and have requirements to respond to TP/PC requests for information to help the PC/TP develop Corretive Action Plans (CAPs).

Jesus Sammy Alcaraz - Imperial Irrigation District - 1

Answer	No
Document Name	
Comment	

For meeting the compliance for Requirement R1 – part 1.1 – subpart 1.1.2 and for Requirement R2 – part 2.1 – subpart 2.1.3, the cooperation of the RC is required by PCs and TPs. But RC is NOT under compliance requirement for this action since the standard is NOT applicable to them. Hence, inaction from RC can expose PCs and TPs to possible violation with these sub-requirements. Instead **IRO-017 Outage Coordination** standard is a better venue to address FERC's concern from Paragraph 40 and **TPL-001** standard should be maintained solely as a *true* Transmission Planning Standard.

Suggestion: Address this in a future revision of IRO-017.

Depending on how R1, Part 1.1.2 and Part 2.1.3 are revised, the RC may have an obligation to provide consultation to the TP/PC, or otherwise the TP/PC can be assessed non-compliant with the part if the RC does not respond to the TP/PC's requests.

If the standard is calling for PC/TP collaboration/coordination, etc. with other functional entities, applicability of the TPL-001-5 standard should also apply to those other entities (e.g. RC) so they have a vested interest in collaborating with the PC/TP.

SDG&E agrees with the SDT, but SDG&E is concerned that the role the RC, TOs, GOs and DPs is not well defined with respect to TPL-001. If the SDT keeps the reference to the Reliability Coordinator in section 1.1.2., then the Reliability Coodinator should be added as an applicable entity.

Scott Downey - Peak Reliability - 1	
Answer	Yes
Document Name	
Comment	
The current proposed standard has requirements that are applicable only to the PC and TP; therefore, it makes sense to have the standard itself applicable only to PCs and TPs. It doesn't make sense to do it any other way. Therefore, the standard needs to remove implied requirements for the RC to consult with the PC/TP.

Answer	Yes
Document Name	
Comment	

The question is inconsistent with commonly used abbreviations for functional entities. What functional entities are the SDT referencing and did not include in the applicability of this standard? Is the SDT attempting to refer to Transmission Owners (TO) versus Transmission Operators (TOP) and Generator Owners (GO) versus Generator Operators (GOP)? Nonetheless, we believe the applicability section should be reflective of only those entities that are required to maintain system models and conduct analytical studies identified within the standard.

Its seems strange to bring the RC into the planning world when the Standard does not apply to that function, and the RC is not a responsible entity. To eliminate this, including potentially adding the RC as a responsible entity in this standard (R1), remove the RC language as proposed above in the response to Question 1. But if the RC is included, our recommendation would be for Requirement 1, Part 1.1.2 to state "request known outages from the RC to be considered for analysis."

The 36 month implementation period is too short of a time to address all requirements except Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions. The 60 month implementation plan for everything doesn't create any confusion on which requirements need to be implemented and gives the planning engineer(s) more time to make sure all requirements are addressed in their annual planning assessment.

Based on our comments requesting additional clarity be provided on redundancy and its levels, as well as what is meant by “single communication system”, we cannot agree with the 36 month implementation period, until said clarification is provided. It is not possible to know if 36 months, or 60 months is adequate unless the scope of work is clearly understood by industry stakeholders. Once additional clarity is provided, expectations will be clearer, and level/scope of work will be more easily determined.

By providing oly 36 months to accomplish these requirements, it would force TOs to essentially perform simulations at all locations, assuming that relay redundancy does not exist anywhere, rather than determine first where relay redundancy does not exist and limit the scope of transient stability simulations to those locations.

SNPD is however, somewhat concerned with the 36 month implementation period to address **All Requirements** except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5, because our budget approval process may require 1-2 years and the construction period may need 5-7 years. It would be more practical for the Drafting Team to suggest an implementation plan with the following items:

- Provide Project Goals and Objectives
- Provide a List of Tasks, and Tentative Schedules

7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

Aaron Cavanaugh - Bonneville Power Administration - 1,3,5,6 - WECC	
Answer	No

Document Name	
Comment	
BPA does not support the requirement for Corrective Action Plans in 4.6, BPA believes it is not economically justifiable to require Corrective Action Plans for low probability extreme events like these. Instead, an effort to minimize the likelihood of cascading should be considered, if studies indicate there is the potential for cascading on critical parts of the system. If Corrective Action Plans are going to be required, BPA agrees that the 60-month implementation plan is appropriate.

TVA agrees with having 60 months for the development of the corrective action plan. However, we do not agree that a corrective action plan should be required for Requirement 4, Part 4.6.

The new language under Requirement R4, Part 4.6 should be deleted all together. It goes far beyond what the conclusion from the analysis from Order No. 754 recommended and will cost the industry a very significant amount of time and money for implementation for a comparatively insignificant improvement in the reliability. Requirement R4, Part 4.5 already addresses this cascading issue for extreme events in the Commission approved and currently enforceable TPL-001-4 standard and should be left as-is. We agree that for the Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4 events, the system still needs to perform reliably and without any planning criteria violation. However, no operational workaround can be performed for any newly identified violation due to this suggested/clarified language for Footnote 13 and capital improvement projects will be the “only” corrective action plans which will require a significant time and effort for coordination among PCs, TPs and the Facility owners and operators (TO/ TOP/ GO/ GOP). In addition, the installation/ implementation of such Corrective Action Plans may cost the industry tens of billions of dollars with significant construction effort spanning 10-20 years. Hence a mere 60 months (5 years) for meeting Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4 implementation and compliance is not adequate. The industry needs to be surveyed again to see the outcome from the studies with the modified/clarified language in 5 years (after 36 months for TPL-001-5 effective date + 24 months to develop corrective action plan) to have a more realistic implementation schedule for the remedies (Corrective Action Plans) for Part 2.7. **Suggestion**: Requirement 4, Part 4.6 is not needed since Requirement R4, Part 4.5 already addresses it. Regarding Requirement 2, Part 2.7, an additional industry survey will be needed to determine a reasonable and appropriate timeline to implement the Corrective Action Plans just for the newly identified shortcomings for P5 events with the proposed/modified Footnote 13.

We (utilities) probably already know that we cannot meet the 60 month implementation period. Capital improvements can not be determined and implemented in a 60 month time period. Forced compliance to 60 months would require undesirable mitigations such as system protection adjustments that	

might reduce system security, misoperations due to changes in protection systems that result in non-standard configurations and changes to maintenance practices due to non-standard application of protection systems.

There is a concern that utilities will not be able to meet the 60 month implementation plan in a reliabile manner. Unlike other potential areas identified in Planning Studies where the system may not meet the System Performance Requirements outlined in Table 1, other temporary reliable solutions, such as the use of Operating Procedures, are available that can be implemented until a long term solution (capital project) is completed. In many instances the only way to fully mitigate impacts resulting from “failure of a non-redundant component of a Protection System” event is to add redundancy. If this cannot be achieved in 60 months utilities may be forced to make undesirable system protection adjustments that could result in a higher rate of misoperations, reduction of system security, and reduced reliability until redundancy can be added. This should not be interpreted as utlities ignoring the importance of adding redundancy at critical points on the system, but implementation should be done on a cost/benefit (risk assessment) basis that takes into consideration the resources individual utilities have to adequately address areas of concerns resulting fromorm single points of failure. In other words, the timing requirement of the implementation plan should not be so prescriptive that it leads to greater reliability risks than the conerns associated with the potential consequences of a single point of failure event.

We believe that a phased approach should be taken to address the concerns for single point of failure. We do not believe that all transmission facilities are of equal value or pose an equal risk to the system. We believe that the risk is generally related to system voltage, and the highest voltage facilities need to be addressed first. Further, we recognize that there are many more lower voltage facilities with non-redundant protection systems that need to be addressed, and these upgrades will likely require the expansion or addition of control buildings to house the additional protection system components.

As stated in question 6, the minimum time for implementation should be 60 months to account for existing plans and budgets. This should be an additional 24-36 months beyond the implementation period for the other requirements. Therefore, the implementation period should be between 84 and 96 months at a minimum.

Comments: Requirement 4, part 4.6, should be deleted. This new requirement goes way beyond	

what was recommended by Order No. 754 and has the possibility to cause undue financial burden to industry without a corresponding benefit to reliability. With regards to Requirement 2, Part 2.7, 60 months for implementation is not sufficient. The possibility of large capital expenditure due to Corrective Action Plans as well as the associated construction timelines makes a 60 month implementation difficult to comply with. A suggestion would be to perform a survey to see what corrective action plans are required after industry has had time to do evaluations and then establish an implementaion timeline.

The implementation period and associated implementation plan are hard to follow. This is an industry wide issue, not just directed this standard. Suggested change would be to put actual dates in place of relate dates identified before the standard is approved. We have no problem with the 60 months as listed.

KCP&L agrees with the “60-month” implementation plan; however, suggests adding language to clarify what the “60-month” period represents. The question implies there is a distinction in the implementation periods for specific Requirements, allowing 60-months for some and something different for other Requirements. We only can guess that the referenced 60-month period reflects the sum of the 36-month assessment period and the 24-month CAP development period. If that is the case, we suggest not using “60-months” and list the allocated implementation periods for each action—assessments, CAP drafting.

Are corrective action plans required to be developed within 60 months or to be completed within 60 months? Assuming the TP/PC takes most of the 36 months to implement the rest of TPL-001-5, the additional 24 months provides very little time for a TO/GO to actually implement construction projects.

: Due to the changes incorporated in this proposed TPL standard, Reliability Standard **CIP-014-2 – Physical Security** can be impacted with the outcome. The proposed TPL-001-5 is setting the bar higher than before for the PCs and TPs. This can result in a different scenario for applicable Transmission Facilities for CIP-014-2 as identified by PCs and TPs (CIP-014-2 – section 4. Applicability – 4.1. Functional Entities – 4.1.1 – 4.1.1.3) in accordance with TPL-001-5 analyses.

Scott Downey - Peak Reliability - 1	
Answer	Yes
Document Name	
Comment	
While there are no specific documents that stand out as being in conflict with the proposed changes, Peak believes that the notion of separation of responsibilities might be compromised with the proposed changes, specifically, responsibilities between the RC and the PC/TP. Perhaps, in this regard, the proposed changes might conflict with the NERC Functional Model. Some of the proposed revisions might be interpreted to pull RCs into the work for which PCs and TPs are responsible, thus implicitly requiring the RCs to perform duties they otherwise would not perform. While on the surface the proposed revisions may appear to be a good idea to improve communications between operations and planning, Peak believes that there are better ways of achieving that objective without creating implied responsibilities for the RC in the planning horizon, where the RC has no direct responsibility. Peak would support revisions to the requirements that do not create implied responsibilities for the RC in the planning horizon.

The proposed changes to sub-requirement 1.1.2 may be in conflict with the standard IRO-017-Outage Coordination, since outage coordination is more of an Operational Planning issue (next day studies up to six months) than a Transmission Planning issue, which covers one to ten year planning horizon.

MH believes that the SDT was unable to capture the proposed recommendations in the background document prepared by NERC SPCS and SAMS. A risk based assessment should be used to identify locations of concern rather than making full protection redundancy a bright line requirement. The background document provided a criteria for busses to be evaluated (Table 1.1) and criteria to evaluate the system performance (Table 1.2).

BPA believes that past performance can be a good indicator of future performance. These types of outages have not been an issue in the past. BPA believes that it is not economically justifiable to require corrective action plans for low probability extreme events like these. Instead, BPA believes an effort to minimize the likelihood of cascading should be considered, if studies indicate there is the potential for cascading on critical parts of the system. BPA believes the penalties are too severe for such low probability extreme events.

The new language under Requirement R4, Part 4.6 should be deleted all together. It goes far beyond what the conclusion from the analysis from Order No. 754 recommended and will cost the industry a very significant amount of time and money for implementation for a comparatively insignificant improvement in the reliability. Requirement R4, Part 4.5 already addresses this cascading issue for extreme events in the currently enforceable TPL-001-4 standard and should be left as-is. **Suggestion**: Since Requirement 4, Part 4.6 is not needed, no corresponding VRF/VSL revised language is needed.

(1) We believe the development a Corrective Action Plan is administrative in nature and constitutes a Lower Violation Risk Factor in the Long-Term Planning Horizon. The proposed requirement to develop a Corrective Action Plan does not have a direct or adverse effect on the electrical state or capability of the BES and does not align with the Medium Violation Risk Factor criteria identified by NERC.	

(2) NERC identifies the criteria for a High VSL as the "performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent." In comparison, NERC identifies the criteria for a Lower VSL as the "performance or product measured almost meets the full intent of the requirement." We propose moving the failure to develop a Corrective Action Plan to the Lower VSL, as the full intent of Requirement R4 focuses more on the performance of Contingency analyses.

The Violation Risk Factor (VRF) and Violation Severity Level (VSL) for Requirement 4, Part 4.6 emphasizes a new level of depth for a Corrective Action Plan in the Stability portion of the Planning Assessment. This seems inconsistent with the VRF/VSLs for Requirement 2, Part 2.7 which focus on creating a Corrective Action Plan for a number of actions already implemented by industry standards. See comments #3 and #4.

Order 786 specifically mentions that TPL-001 is intended to analyze the Near-Term Transmission Planning Horizon and requires annual assessments using Year One or Year Two, and Year Five. We agree that 1-, 2-, and 5-year forward looking is the appropriate and intended timeframe to be evaluated by the requirements of TPL-001. Therefore, only outages planned for this timeframe (more than 12-months forward) are appropriate to require analysis as a Standard Requirement of Transmission Planning such as TPL-001. Anything less than 1-year belongs to the Operations timeframe.

The modified verbiage for Part 2.1.3 includes the phrase “as selected in consultation with the Reliability Coordinator” – this modification is unnecessary and causes confusion. It is not clear why Part 2.1.3 needs to be modified at all. Further, including this phrase in Part 2.1.3 makes it inconsistent with the verbiage in Part 2.4.3 If the standard is calling for PC/TP consultations with other functional entities (RC), applicability of the TPL-001-5 standard should also apply to those other entities so those entities have a vested interest in collaborating with the PC/TP. Otherwise the other entities have no obligation to participate. Finally, NERC should undertake a complete refurbishment of the standard, with NERC holding technical discussions in an open forum to address all the ambiguities presently left to interpretation.

1) Both additions in the stability analysis section (R2.4.3 and R2.4.5) need to reference or somehow incorporate R4.4 and the ability of the PC or TP to identify and simulate only those events that are expected to produce the most severe System Impacts. This allows the PC and TP to maintain some semblance of engineering judgment and avoid conducting an un-bounded number of simulations. 2) The drafting needs to correct the cross reference from R2.7 to R2 part 2.4.3 as the proposed revisions re-number 2.4.3 to 2.4.4.	

Thank you again for the efforts of the SDT and we appreciate the opportunity to provide comment. We hope the comments are found to be helpful.

In Part 1.2 of section C on page 16, the new language identifying the Measures for which the responsible entity must retain evidence of compliance appears to incorrectly exclude Measure M8. Further, the corresponding changes to IRO-017 relative to R 1.1.2 as recommended in the PC report to the drafting team (excerpt below) should also be pursued: • Use the coordination process developed pursuant to IRO-017-1 Requirement R1 to direct how ALL known scheduled outages are reviewed and the actions that must be taken. The following objectives should be added to R1: · Describe how the review of known scheduled outages by the RC, PC, TO, and TP will be integrated into the Near Term Assessment of the Planning Horizon required by TPL-001-4, and whether and which of these known scheduled outages will be studied in this Assessment. · Describe how emerging challenges and the inability to schedule outages will be communicated from the TO and RC to the TP and PC to be addressed in a future Corrective Action Plan pursuant to TPL-001-4.

We have a question: The proposed implementation plan makes reference to, in certain circumstances, carrying over from TPL-001-4 the 84-month exception (our word) period related to Corrective Action Plans including Non-Consequential Load Loss and curtailment of Firm Transmission Service. We are unclear how the 84-month exception will impact, correlate or align with TPL-001-5's proposed 36-month assessment period and the 24-month CAP drafting period?

In regards to Requirement 5:

There is academic and industry documentation used to define what is “acceptable” related to steady state voltage limits and transient voltage response. The documentation demonstrates negative impact to the transmission system and/or electrical equipment as result of transient voltage remaining below a certain threshold for a certain time-frame, as well as for steady state voltage being either too high or too low.

Georgia Transmission Corporation has not found any academic or industry documentation that suggests that there is a negative impact to either the transmission system or electrical equipment related to steady state voltage deviation.

There is a lack of information to document that steady state post-Contingency deviation (the difference between pre-Contingency steady voltage and post-Contingency steady state voltage) beyond a certain limit has a negative impact on either the transmission system or electrical equipment. Consequently, Transmission Planners and Planning Coordinators will be required to develop a Corrective Action Plan to address system conditions that fall outside of voltage deviation criteria that have no real impact on system reliability. Therefore this voltage deviation criteria should be eliminated.

We agree that the data request and analysis after Order No. 754 was a good first step towards addressing the single points of failure in the protection system and the proposed language in TPL-001-5 is an improvement upon that criteria. The added/clarified language in the draft TPL-001-5 for P5 and stability performance extreme events 2e-2h along with footnote 13 will, however, require the PCs and TPs to perform a lot more analyses than was originally performed for Order No. 754 data request.

The criteria for buses to be tested (Table A; reproduced below) under Order No. 754 data request required 4 or more circuits at 200 kV or higher, and, 6 or more circuits between 100 kV to 200 kV. However, the assessment according to the proposed TPL-001-5 requires ALL BES buses; regardless of how many circuits terminate at each BES bus; to be tested. Due to this more in-depth analyses now required, there will definitely be a significant new findings for P5 Planning events for which the performance requirement is more restrictive than the performance measure (Table C; reproduced below) under data request. Before the industry assesses the entire BES (implementation plan: 36 months) followed by the development of the Corrective Action Plans just for P5 events with the proposed Footnote 13 (implementation plan: additional 24 months); it will be very pre-mature at this time to grant 60 months for the Corrective Action Plan implementation. It will be logical to have another survey/data request performed after 60 months from the initial implementation of the proposed standard (36 months analyses + 24 months Corrective Action Plan development). Then, depending upon the outcome, a more realistic implementation plan for the Corrective Action Plans can be developed. The Corrective Action Plan for the extreme events Requirement R4, Part 4.6 should be completely removed; along with the corresponding VRF/VSL languages; from the proposed standard as this is already addressed by the Commission approved TPL-001-4 Requirement R4, Part 4.5.

Duke Energy recommends that when providing addiotional clarity/rationale on the subject of redundancy, the drafting team consider referring to a technical paper developed by the System Protection Control Task Force developed in 2008 titled: “Protection System Reliabilty: Redundancy of Protection System Elements”. Some aspects of this document may be helpful in providing additional clarity on this topic for the industry.

(1) The Standards Authorization Request associated with this project provided the SDT an opportunity to evaluate requirement retirements under Paragraph 81 criteria. We believe Requirements R5, R6, R7, and R8 fall under such criteria. Documenting acceptable voltage limits and deviations and defining instability criteria for Cascading and uncontrolled islanding events are all necessary, yet are likely documented as assumptions and technical rationales listed within Planning Assessments. Moreover, these criteria are not directly associated with the required execution of conducting studies. The identification of study coordination roles and responsibilities through meeting minutes and distribution of Planning Assessment results to appropriate entities within a specific time period are administrative activities. Further proof is that these requirements do not have performance-based VSLs identified, particularly R8 which doesn’t even have a VSL identified at all. (2) The proposed Evidence Retention period identified within the standard does not identify Measure M8. (3) We thank you for this opportunity to provide these comments.

Similar to the comments provided in Question 2 for Requirement 2, Part 2.4.5, NVE has concerns about possible resource issues for performing a dynamic analysis for all P1 events. NVE feels that the transmission planners should continue to use their engineering judgment and discretion to select which contingencies make the most sense to study for their system for the dynamic analysis.

Scott Downey - Peak Reliability - 1

Answer	Yes
Document Name	
Comment	

The comment form did not ask of entities agreed with the proposed changes to requirement R2.1.3, so Peak is providing those comments here. Peak does not agree with the proposed revisions in requirement R2.1.3. The proposed revision states, *"[Qualifying studies need to include the following conditions:] R2.1.3. P1 events in Table 1, **as selected in consultation with the as directed Reliability Coordinator**, with known outages modeled as specified in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled."* Peak disagrees with this proposed revision for many of the same reasons we disagree with the proposed changes to requirement R1.1.2. Overall, both proposals involve the RC in matters that are outside the RC's timeframe of assessment responsibility.

Additionally, the proposed requirement R2.1.3 is confusing to Peak. Is this standard requiring the RC to be consulted to determine ***which*** single P1 Contingencies the PC/TP needs to include in their studies? It is unclear to Peak exactly what the proposed changes to this requirement is trying to accomplish.

Peak as an RC requires operations reliability for ***all*** P1 Contingency events…not just ***certain*** ones. Involving the RC in the selection of P1 Contingencies that a given PC/TP should include in their studies is burdensome for RCs and does not provide any tangible reliability benefit. This proposed requirement creates an implied expectation for the RC to have already performed some kind of screening of P1 events and for the RC to relay any critical P1 performance related issues to the PC/TPs as part of the proposed consultation. Peak believes that this kind of analysis is above and beyond the expectations for RCs today, and that the standard should in no way create such an implied responsibility for RCs. Peak believes that identifying the P1 Contingencies that should be included in a PC/TP's Planning Assessment is purely a PC/TP responsibility and should not involve RCs explicitly in the standard.

By default, proposed requirement R2.1.3 requires the RC to do something in order for the TP/PC to be compliant – which in effect is a requirement for the RC. Peak believes this is not a good approach for writing standards. If the RC does not participate in this consultation, or if the consultation is "weak", is the PC/TP faced with a potential compliance ramifications? If such is the case, is the RC subject to any compliance ramifications?

Additionally, given the high number of PCs and TPs in the Western Interconnection, it is impractical for the Peak as an RC to have a prominent role in the determination of the P1 Contingencies a given PC/TP should include in their studies.

Requirement 2 – 2.7.1: the reference to Special Protection Systems (SPS) should be replaced by Remedial Action Schemes (RAS).

Requirement 4 – 4.1.1: the reference to Special Protection Systems (SPS) should be replaced by Remedial Action Schemes (RAS).

Order 786 specifically mentions that TPL-001 is intended to analyze the Near-Term Transmission Planning Horizon and requires annual assessments using Year One or year two, and year five. We agree that 1-, 2-, and 5-year forward looking is the appropriate and intended timeframe to be evaluated by the requirements of TPL-001. Therefore, only outages planned for this timeframe (more than 12-months forward) are appropriate to be required to be analyzed as a requirement of a Transmission Planning standard such as TPL-001.

Outages planned to occur within the next 12-months should be analyzed per the Operations Planning requirements of IRO-017 which is intended to cover the Operations Planning

time horizon. Using a bright-line of 12-months to determine the applicability of IRO-017 vs TPL-001 gives clarity and certainty of the appropriate requirements to be met.

When analyzing single-point-of-failure contingencies for protection schemes under three-phase faults as extreme events, it is important to note that a particular scheme could be fully redundant for three-phase faults whereas it is not redundant for single-phase-to-ground faults. For example, when three-phase faults are considered, there will be three current transformers involved and perhaps three relay units involved (particularly for lines protected by electromechanical relay units, which are often single-phase units), and if these components are the only sources of non-redundancy for a P5 contingency evaluated for a single-phase-to-ground fault, the scheme may not be applicable to single-point-of-failure for evaluating three-phase faults as an extreme event. The wording of the standard should ensure that this distinction can be made.

WAPA believes there is risk with the proposed changes of the single point of failure (SPF) language that will not significantly improve reliability. There is likelihood this change may even reduce reliability by having the CAPs force entities to redirect its limited resources away from other important reliability needs to solve SPF identified issue. Further, implementation of the CAPs may likely cause significant mis-ops while system protection systems are being modified to eliminate SPFs thus reducing reliability and increase risk to the transmission system. Frequency of these SPF events are so seldom, they do not warrant the cost to eliminate unless there are significant risks to the transmission system such as instability and cascading. No data has been provided to demonstrate that SPFs have been a significant factor in system outages.

BPA believes the drafting team should consider the economical impact of requiring Corrective Action Plans for low probability extreme events, especially if the type of events have not occurred in the past or are not known to cause severe consequences.

BPA has suggested edits to the requirement language for the following:

R1.1.2. Known outage(s) of generation or Transmission Facility(ies) as selected in consultation with its Transmission Operator for outage durations that occur in the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and R. 2.4.3

R2.1.3. P1 events in Table 1, as selected in consultation with its Transmission Operator, with the known outages modeled as specified in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

R4.6. If the analysis concludes there is Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

R4.6.1 and **R4.6.2** deleted.

The SDT should consider changing the purpose statement of TPL-001 (section A.3). It identifies the wrong goal. The "Purpose" of the requirement is not to establish a requirement. The purpose of the requirement is to ensure that the Bulk Electric System will have the resources necessary to meet system load while also meeting performance requirements. This is done by requiring the TP/PC to assess the future (forecasted) system needs of its portion of the Bulk Electric System using software tools.

The SDT should consider limitations on available data, the capabilities of analysis software (power flow, dynamics and short circuit) and the burden placed on the TP/PC. (More paperwork does not translate into better reliability).

Although it is not specified as part of the scope if this project, Texas RE is concerned the standard does not require studying unknown outages in off-peak conditions in addition to the known outages. Studying all conditions, known and unknown, addresses the “planned maintenance outages of significant facilities” in FERC order 786, paragraph 40. Even routine maintenance outages that occur during off-peak load conditions could be significant, but TPs and PCs may not have the information needed to meet the “known” requirement when TPL studies are being performed.

John Merrell – Tacoma Public Utilities (Tacoma, WA) - 3	
Answer	Yes
Document Name	
Comment	
1. Footnote 13.4 has numerical issues. As explained above, Tacoma Power would prefer explicit requirements for each of the 5 bullet points in the Protection System Definition. If 13.4 is kept, it should be revised to say “A single control circuitry path associated with protective functions between the DC panel and a trip coil of the circuit breakers or other interrupting devices.” In the current draft, it is unclear whether there is a requirement to have dual trip coils. 2. The combination of a P1 event in Table 1 and known outages modeled as in Requirement R1, Part 1.1.2 is not a single contingency. Thus, the system performance requirement should be less stringent than for a P1 event. For these types of events, interruption of Firm Transmission Service and Non-Consequential Load Loss should be allowed.

Unofficial Comment Form

Project 2015-10 Single Points of Failure
TPL-001-5

Do not use this form for submitting comments. Use the electronic form to submit comments on **TPL-001-5 – Transmission System Planning Performance Requirements** . The electronic form must be submitted by **8 p.m. Eastern, Wednesday, May 24, 2017.**

Additional information is available on the project page. If you have questions, contact Standards Developer, Latrice Harkness (via email), or at (404) 446-9728.

Background Information

The SPCS and the SAMS conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action**.**

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Questions

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

   ☐ Yes
   ☒ No

   Comments:
   Corn Belt agrees with the SPP Standards Review Group and its clarification of an important issue regarding the expectations of regulatory staff on the impacts of Requirement 1, Part 1.1.2. The clarification is about the differences in power flow case topologies used by SPP Operations and SPP Planning. Issues found in the operating horizon would be specific to that point in time and would take into consideration any planned outages, forced outages, generation dispatch, transfers, and load levels that would cause concerns. These operating horizon variables would be changing from minute to hour to day to week to month to season to year. The same outage placed in a planning horizon assessment would be placed into a model that has a lot fewer outages, different generation dispatch, different transfer levels, and different load levels. The topology differences between the two power flow models is significant enough that the operation horizon outages would more than likely not cause issues in the Transmission System Planning Performance Requirements (TPL) Assessment. Further, the SPP Standards Review Group states that trying to mimic, follow, or forecast these operating horizon outages in a meaningful manner would be a moving target. This is due to the fact that most of the planned outages are due to maintenance and capital projects that usually do not re-occur within a 3-5 year period, if ever. The SPP Standards Review Group also found the proposed language to be vague and ambiguous, regarding the timeframe, and therefore would be hard to defend during an audit.

   Corn Belt agrees with the SPP Standards Review Group that the language is unclear as to whether outages should be evaluated only in the season for which they are planned or whether they should be evaluated for the peak or off-peak 1 or 2, and 5 planning horizon. In addition, the reference to the number of additional cases and the associated seasons that could be required. Corn Belt agrees with the SPP Standards Review Group suggested proposed language that would tie this process to the TOP Standards instead of the TPL Standards as this is pertaining more to operation related issues.

   Also concerned that this could significantly increase the number of near term cases created and studied and add significant work load to tune L&R for these cases. Concern this will significantly increase PC/TP study work load without benefit due to undetermentant amount of outages that need studied. Even though the 6 month duration may not be perfect, it did provide specific criteria to select outages to study. Concern this change will result in significant wasted time and effort to produce results that won't ultimately be used because the same outages will be restudied in ops horizon.

Firmly disagree with the bullet in the Rationale for Requirement R1 Part 1.1.2. "Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages (see P 44);" Category P3 and P6 does sufficiently cover most maintenance outages any utility would expect and the criteria for R1.1.2 should define outages beyond those that are normaly studied as Category P3 and P6.

Futher, the word "limited" in the comment form Question 1 above is not in the proposed language of R1.1.2, and is misleading by implying the intent is for a "small number of" outages. If the intent is for the PC/TP's to study only a limited amount of outages (beyond those already studies as P3 and P6's) then edit the language to state so.

Outages of concern to be studied separately. Base case assumptions.[A1]

Suggested Language:[A2]
R1.1.2 Known critical outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?

☒ Yes
☐ No

Comments: : Corn Belt agrees, but suggests that "more than 1 year" be substituted for long lead time throughout TPL-001-5 where appropriate for better clarity.

Concerns that the number of additional dynamic analyses to include long lead time items taking more than 1 year for P1 and P2 needs to be bounded. There are real computational constraints that could take months to run. An example could give the Transmission Planner discretion to chose the worst conditions.

3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?

☐ Yes
☒ No

Comments:

Recommend that “Cascading” be replaced with a specific MW number such as the loss of 2,000 MW of generation as referenced in the EOP-004 standard. The term “Cascading” remains too vague and subject to change. A MW threshold is a better “bright line” criteria.

Recommend each BES Protection System component class be covered explicitly in Footnote 13 along with an inclusion or exclusion justification. Abrief Protection System scope for Footnote 13 may also be helpful.

Ask if relays should be limited to electromechanical relays as the SPCS/SAMS Order 754 report identified risk depends upon the relay type and protection system design
(meaning multiple relays to respond to a fault). If an entity shows no electromechanical primary or aux relays can that be sufficient to exclude from being redundant?

Ask if communications systems should be eliminated except for RAS. The SPCS/SAMS Order 754 report identified communications systems posed a lower risk level.

Example NERC Defined Protection System Component Classes, Scope and Applicability:

NERC Bulk Electric System (BES) protective relays/sudden pressure relays/reclosing relays:
NERC BES PRC-005-6 Protection System electromechanical primary and auxillary relays are included in footnote 13. This includes PRC-005-6 identified sudden pressure and reclosing relays.

NERC BES associated communication systems:
NERC BES PRC-005-6 associated communication systems are included in footnote 13.
Redundant communications system for footnote 13 would be two communications channels. Redundant communications for Footnote 13 does not require separate and diversely routed communications towers.

NERC BES Voltage and current sensing devices:

NERC BES PRC-005-6 voltage and current sensing devices are not included in footnote 13. The SPCS/SAMS Order 754 report identified that voltage and current sensing devices were robust and posed a lower risk level.

NERC BES Station batteries:

NERC BES PRC-005-6 Station batteries are included in footnote 13 with the following exceptions. A single station DC supply is allowed if monitored for low voltage and open
circuit alarms to a centrally monitored location within 24 hours of abnormal condition detection.

NERC BES Battery Chargers:
NERC BES PRC-005-6 station battery chargers are included in footnote 13. A single station charger is allowed if the battery bank is monitored for low voltage and open circuit
alarms to a centrally monitored location within 24 hours of abnormal condition detection.

NERC BES DC control circuitry:
NERC BES PRC-005-6 DC control circuitry is included in footnote 13 but its outcome is already considered in the P4 stuck breaker category. Whether stuck breaker of a DC control circuit failure, the end result is the same.

4. Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?

   ☐ Yes
   ☒ No

   Comments:
   The additions which require a Corrective Action Plan for the subset of Table 1 extreme events (footnote 13, 2e-2h) are beyond what is stated in the conclusion of the SPCS and SAMS “Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request” report. This report recommended the following:

   Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads “[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2.”

Corrective Action Plans for low probability extreme events should not be required. However, it is reasonable that if Cascading is caused by the occurrence of an extreme event, an evaluation of possible actions designed to reduce the likelihood be conducted, as is currently stated in TPL-001-4 for extreme events (R4.5). Based on the conlusion of the above mentioned SPCS and SAMS report, it is understood that the intent should be to clarify that **both** three-phase faults with stuck breaker **and** failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing shall be considered as part of those extreme events in Table 1 that are expected to produce more severe System impacts in accordance with the existing language of TPL-001-4 R4.5. In other words, clarify that the "or" in Table 1 – Extreme Stability Events should not be interpreted as you only need to consider either stuck breaker or relay failure in R4.5. This is accomplished by simply breaking these events apart in Table 1 as shown below (and as in the current TPL-001-5 draft):

2. Local or wide area events affecting the Transmission System such as:
   a. 3Ø fault on generator with stuck breaker[10] resulting in Delayed Fault Clearing.
   b. 3Ø fault on Transmission circuit with stuck breaker[10] resulting in Delayed Fault Clearing.
   c. 3Ø fault on transformer with stuck breaker[10] resulting in Delayed Fault Clearing.
   d. 3Ø fault on bus section with stuck breaker[10] resulting in Delayed Fault Clearing.
   e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   h. 3Ø fault on bus section with failure of a non-redundant comoponent of a Protection System[13] resulting in Delayed Fault Clearing.
   i. 3Ø internal breaker fault.
   j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

To further emphasize this point, refer to the alternatives for addressing reliability risks associated with single points of failure outlined in Charper 2 of the SPCS and SAMS report:

- *Place additional emphasis on assessment of a three-phase fault and protection system failure*
  - *Provideds assurance that areas where a three-phase fault accompanied by a single point of failure that will cause an adverse impact are identified and evaluated*
- *Elevate to a planning event with its own system performance criteria*

   - *Probability of three-phase fault with a protection system failure is low enough that it does not warrant a planning event*
- *Keep as an extreme event with no change (other than footnote 13)*
   - *Does not provide assurance a three-phase fault with protection system failure is studied in planning assessments*

From the above language describing the considered alternatives, it can be ascertained that the concern is ensuring that the language in the standard be updated to assure three-phase faults with protection system failure are studied in planning assessments, not that a "subset of Table 1 Extreme Events" be created that are treated differently than other Extreme Events by elevating them to requiring Corrective Action Plans because "the probability of three-phase faults with a protection system failure is low enough that it does not warrant a planning event". Furthermore, there is no technical justification to elevate a three-phase fault with failure of a non-redundant component of a Protection System events above three-phase fault with stuck breaker events.

Although Corn Belt strongly disagrees with requiring a Corrective Action Plan for this "subset of Table 1 extreme events", if this requirement is carried forward Corn Belt recommends creating a separate P8 Event for these three-phase failure of a non-redundant component of a Protection System events because it makes Table 1 clearer to read, understand and differentiate between what is required of these events compared to other Extreme Events.

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability (all events): a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. d. Simulate Normal Clearing unless otherwise specified. e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only (P0 through P7 events only)**: f. Applicable Facility Ratings shall not be exceeded. g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. h. Planning event P0 is applicable to steady state only. i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only (P1 through P7 events only):** j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P8 Multiple Contingency *(Fault plus non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6] 5. Bus Section	3Ø	EHV, HV	Yes	Yes

5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))

☐ Yes
☒ No

Comments: Corn Belt agrees with the SPP Standards Review Group proposal that a standard applicable to the Reliability Coordinator (RC) address RC requirements should be considered. Potentially, it could be added to NERC Stanadard IRO-017.

Corn Belt agrees with the SPP Standards Review Group suggestion that the Transmission Owners (TOs) and Generator Owners (GOs) should be added to the applicability section of the standard and have requirements to respond to TP/PC requests for information to help the PC/TP develop Corretive Action Plans (CAPs).

6. Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?

☒ Yes
☐ No

Comments: As long as the implementation plan refers to the development of required CAPs, not the placing the required CAPs in service.

7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

☐ Yes
☒ No

Comments:

We (utilities) probably already know that we cannot meet the 60 month implementation period. Capital improvements can not be determined and implemented in a 60 month time period. Forced compliance to 60 months would require undesirable mitigations such as system protection adjustments that might reduce system security, misoperations due to changes in protection systems that result in non-standard configurations and changes to maintenance practices due to non-standard application of protection systems.

There is a concern that utilities will not be able to meet the 60 month implementation plan in a reliabile manner. Unlike other potential areas identified in Planning Studies where the system may not meet the System Performance Requirements outlined in Table 1, other temporary reliable solutions, such as the use of Operating Procedures, are available that can be implemented until a long term solution (capital project) is completed. In many instances the only way to fully mitigate impacts resulting from "failure of a non-redundant component of a Protection System" event is to add redundancy. If this cannot be achieved in 60 months utilities may be forced to make undesirable system protection adjustments that could result in a higher rate of misoperations, reduction of system security, and reduced reliability until redundancy can be added. This should not be interpreted as utlities ignoring the importance of adding redundancy at critical points on the system, but implementation should be done on a cost/benefit (risk assessment) basis that takes into consideration the resources individual utilities have to adequately address areas of concerns resulting from~~orm~~ single points of failure. In other words, the timing requirement of the implementation plan should not be so prescriptive that it leads to greater reliability risks than the conerns associated with the potential consequences of a single point of failure event.

8. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

   ☐ Yes
   ☒ No

   Comments:

9. Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?

   ☒ Yes
   ☐ No

   Comments:

10. Do you have any other general recommendations/considerations for the drafting team?

☒ Yes
☐ No

Comments:
Corn Belt agrees with the NSRF concerns that the number of additional dynamic analyses for P1 and P2 needs to be bounded in some reasonable fashion for Requirement 2, Part 2.4.5.

Since NERC Protection Systems are referenced, the NSRF recommended that the same PRC-005-6 exclusions for individual wind and solar generators be added to the applicability section:

From PRC-005-6:

4.2.6 Protection Systems and Sudden Pressure Relaying for the following BES generator Facilities for dispersed power producing resources identified through Inclusion I4 of the BES definition:

4.2.6.1 Protection Systems and Sudden Pressure Relaying for Facilities used in aggregating dispersed BES generation from the point where those resources aggregate to greater than 75 MVA to a common point of connection at 100kV or above.

Also noted that the reliability impacts from actual extreme stability 2e-2h events are expected to be much less severe than the reliability impacts found in the FERC Order 754 analyses because the Order 754 analyses did not take into account the operation of bus tie breakers, which significantly reduce the extent of contingencies that involve bus sections.

Unofficial Comment Form

Project 2015-10 Single Points of Failure
TPL-001-5

Do not use this form for submitting comments. Use the electronic form to submit comments on **TPL-001-5 – Transmission System Planning Performance Requirements** . The electronic form must be submitted by **8 p.m. Eastern, Wednesday, May 24, 2017.**

Additional information is available on the project page. If you have questions, contact Standards Developer, Latrice Harkness (via email), or at (404) 446-9728.

Background Information

The SPCS and the SAMS conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action**.**

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Questions

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

   ☐ Yes
   ☒ No

   Comments: 1. IRO-017-1 already requires the RC to maintain a coordination process for the Near-Term Transmission Planning Horizon. The proposed approach in TPL provides little guidance to the RC/TP/PC as to what level of detail to model future outages. This may lead to widely varying practices across regions.

   2. We support the other approaches suggested by FERC to limit the scope based on both time and outage significance. The proposed alternate for R1.1.2 is:
   Schedule outage(s) of Generation or Transmission Facility(ies) that are identified by the Reliability Coordinator, Planning Coordinator, or Transmission Planner as critical to the derivation of Interconnection Reliability Operating Limits (IROLs) and lasting longer than 90 days.

   3. It is important to note the difference between a planned outage in the sense: (1) that maintenance crews "plan" for insulation testing of every transformer every three years, and (2) that a nuclear plant plans to be offline for refueling from exactly 3/3/2019 @ 19:30 to 9/15/2019 08:00. In the former case, the exact outage dates are both unknown and highly flexible, whereas with the latter the outage has specific dates that can be modeled and it must occur regardless of system conditions. The previous 6 month limit served as a screen to identify only those outages which were likely to occur during critical system conditions. Most maintenance is scheduled to avoid system peaks.

   4. It unclear how to model planned outages in year one, year three or year four if the TPL planning assessment uses year two and year five.

2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?

   ☐ Yes
   ☒ No

3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?

☐ Yes
☒ No

Comments:
1. Tacoma Power does not agree that all parts of the Protection System should be treated identically with regards to single point failures. As identified the order 754 final report, some protection system components such as protective relays, auxiliary relays, and DC circuits downstream of the DC panel branch circuit protection have been documented as common causes of actual single point failures. The final report also identifies that AC inputs and the station DC supply pose much lower risk of failure to trip. The attached table shows an alternative set of contingencies that would implement a more risk-based approach to single point failures of each kind of component in the protection system.

2. Tacoma Power proposes P5 include the more common kinds of failures of the protection system that include 1) Protective relays which respond to electrical quantities; 2) A single communications system, necessary for correct operation of protective functions, which is not monitored; and 3) Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

3. New P8 and P9 contingencies for EHV facilities would address the remaining less likely to fail components of the protection system including (1) Voltage and current sensing devices providing inputs to protective relays, (2) Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply). Since these kinds of components are less likely to fail, allowing interruption of firm transmission service and nonconsequential load should be allowed for all voltage levels.

The 754 report found that only 0.7% of 100-199 kV buses had adverse system response from a single point of failure whereas 20% of EHV buses had adverse system response from a single point of failure. This disparity indicates efforts mitigating single component failures should be focused on the EHV system. The new P8 and P9 (i.e. the proposed d-h extreme events) should apply to just EHV elements.

Creating new events P8 and P9 would clarify that Corrective Action Plans are required for these contingencies whereas extreme events do not require CAPs.

4. Tacoma Power supports reformatting of Table 1, as it is currently quite confusing.

5. There appears to be confusion as to whether to monitor protection circuits, the battery bank or the main DC breaker for open circuit. Trip coil monitoring does not provide any assurance the batteries are connected. Furthermore, there appears to be a lack of publicly available evidence

that battery open circuit monitoring substantially lowers the risk of the protection system failing to trip. Dual batteries may be more appropriate for many EHV applications.

6. Battery monitoring system cost roughly the same amount as the set of batteries they monitor. Imposing additional costs for battery monitoring systems may lead to utilities replacing battery banks less often.

7. If the SDT continues to include monitoring as a viable option, these additional clarifications are need: (1) battery open circuit monitoring is required, (2) every breaker/fuse in the DC system must be monitored if it is a single point of failure, (3) a single trip coil is a single point of failure and is not mitigated by having trip coil monitoring unless there is independent breaker failure control circuitry, (4) low voltage monitoring threshold for battery voltage shall be coordinated with the battery design to give indication with at least 50% of battery capacity remaining, (5) auxiliary type relays for loss of DC may not be sufficient for low voltage monitoring of the battery, although they may be used for monitoring for loss of DC, and (6) non-battery-based DC systems require redundancy and should be addressed in a separate bullet under Footnote 13.

8. If monitoring of Protection System components is counted for purposes of TPL-001-5, is it the drafting team's intent that an entity would be obligated to maintain the alarming paths and monitoring systems under PRC-005-6 (Requirement R1, Part 1.2, and Table 2)? An entity should be allowed to consider monitoring for purposes of TPL-001-5 but treat the associated Protection System component(s) as unmonitored for purposes of PRC-005-6.

9. Additional clarification is requested on the demarcation between station DC supply and control circuitry for purposes of TPL-001-5. It is recommended that the main breaker of DC panels be considered part of the station DC supply.

4. Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?

☐ Yes
☒ No

Comments: Tacoma Power disagrees with the concept of requiring CAPs for extreme events. If events are critical enough to need a CAP, they should be listed as required contingencies. Please see our comments to question 2 with regard to which events at which voltage levels should have CAPs.

5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))

☒ Yes
☐ No

Comments: Tacoma Power agrees with the drafting team, provided that the Reliability Coordinator's role under Requirement R1, Part 1.1.2, is only advisory.

6. Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?

☐ Yes
☐ No

Comments:

7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

☐ Yes
☒ No

Comments: Are corrective action plans required to be developed within 60 months or to be completed within 60 months? Assuming the TP/PC takes most of the 36 months to implement the rest of TPL-001-5, the additional 24 months provides very little time for a TO/GO to actually implement construction projects.

8. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

☐ Yes
☒ No

Comments:

9. Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?

☐ Yes
☐ No

Comments:

10. Do you have any other general recommendations/considerations for the drafting team?

☒ Yes
☐ No

Comments: 1. Footnote 13.4 has numerical issues. As explained above, Tacoma Power would prefer explicit requirements for each of the 5 bullet points in the Protection System Definition. If 13.4 is kept, it should be revised to say “A single control circuitry path associated with protective functions between the DC panel and a trip coil of the circuit breakers or other interrupting devices.” In the current draft, it is unclear whether there is a requirement to have dual trip coils.

2. The combination of a P1 event in Table 1 and known outages modeled as in Requirement R1, Part 1.1.2 is not a single contingency. Thus, the system performance requirement should be less stringent than for a P1 event. For these types of events, interruption of Firm Transmission Service and Non-Consequential Load Loss should be allowed.

Background Information

The SPCS and the SAMS conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action**.**

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Questions

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

☐ Yes
☒ No

Comments:

WAPA agrees with the intent to include significant impactful outages that are important to evaluate ahead of what is covered in the Operations Horizon, but we need to ensure that the language change to Requirement 1, Part 1.1.2 supports this intent. It is essential that the scope of outages be limited to significant planned outages that are not hypothetical in nature. Otherwise, there is a concern that this could significantly increase PC/TP study work without an appreciable benefit due to an undeterminant amount of outages that need to be studied. Outage scheduling changes could occur potentially leading to the results from the R1.1.2 analysis becoming irrelevant as it gets closer to when the outage will actually occur (Operations Horizon). These outages will need to be restudied in the Operations Horizon using more accurate information anyway. Even though the 6 month duration may not be perfect, it did provide specific criteria to select outages to study. There is a risk that the proposed language change to R1.1.2 could lead to it being left wide-open regarding what should be included in a Planning model because there are no parameters on what constitutes a significant planned outage.

WAPA disagrees with the bullet in the Rationale for Requirement R1 Part 1.1.2. “Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages (see P 44);” Category P3 and P6 does sufficiently cover most maintenance outages any utility would expect and the criteria for R1.1.2 should define outages beyond those that are normaly studied as Category P3 and P6.

Futher, the word “limited” in the comment form Question 1 above is not in the proposed language of R1.1.2, and is misleading by implying the intent is for a “small number of” outages. If the intent is for the PC/TP’s to study only a limited amount of outages (beyond those already studies as P3 and P6’s) then edit the language to state so.

Suggested Language (add a qualifier to specify these outages should be critical/significant in nature and leave the ultimate decision upon what constitutes a significan planned outage to the PC/TP per R1 that, “shall maintain System models… to complete its Planning Assessment”):

R1.1.2 Known **critical** outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?

   ☒ Yes
   ☐ No

   Comments:

3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?

   ☐ Yes
   ☒ No

   Comments:

   WAPA agrees with the intent but offers improvements to the language.

   In Order No. 786 (P69), FERC declined to direct that NERC revise this standard to apply to all protection system components, at least until NERC completed its analysis of the Order No. 754 data responses. After review of that data, the NERC SPCS and SAMS recommended including protective relays, DC control circuitry, and station DC supply in the standard. This recommendation was based on the survey results regarding the prevalence of non-redundant protective equipment and the simulated disturbance magnitude of a failure of non-redundant equipment. The SPCS and SAMS report, did not, however, quantify the likelihood of each type of non-redundant protection component failure. Thus, it is hard to fully agree with the SPCS/SAMS recommendations at this time (and the Standard Authorization Request is only to "consider" them rather than "address" them).

WAPA does not believe that it is necessary to include analysis of all of these non-redundant Protection System component failures in the TPL standards at this time. Alternatively, if they are included, then they should be treated similarly to the current treatment of Extreme Events where there are no strict performance requirements or mandates to create Corrective Action Plans. In fact, the SPCS and SAMS report suggested that auxiliary relay and lockout relay failures were the main culprit in previous disturbances but failures of other equipment are generally rare or unimpactful (p.7). If anything, the P5 category expansion should be limited to auxiliary and lockout relays. This would allow utilities to focus their money and attention to mitigating the most severe potential impacts rather than building redundancy into systems where it will most likely never be needed.

WAPA recently studied the cost of eliminating single points of failure at a typical older substion. WAPA estimates that building full redundancy will likely cost over $1.3 million and take about a year and a half to implement. The main reason why it takes this long is due to scheduling outages. During outage timeframes, WAPA may have to curtail transmission or generation schedules, which many WAPA customers and staff would view as a decrement to reliable operations. The commissioning of new relays also requires significant testing, which conceivably puts WAPA at greater risk for human error. Furthermore, WAPA does not have any record of a P5 or EE2d type of event in the last 50+ years. Just building redundancy into substations will be a challenge to explain to WAPA ratepayers, and it may prove extremely difficult if WAPA is required to add costs and time for DC control circuitry equipment. Instead, WAPA may desire to focus its limited resources on developing replacement plans for aging equipment (e.g. transformers) or improving security measures.

As a reference, here is the language from SAMS Table 1.3. *DC Control Circuitry: The protection system includes two independent DC control circuits with no common DC control circuitry, auxiliary relays, or circuit breaker trip coils. For the purpose of this data request the DC control circuitry does not include the station DC supply or the main DC* *distributionpanel(s), but does include all the DC circuits used by the protection system to trip a breaker, including any DC control circuit (branch) fuses or breakers at the main DC distribution panel(s).*

In addition to the concerns mentioned above, WAPA suggestions the following clarification of components of a protection system (Footnote 13).

Suggested Language:
For purposes of this standard, non-redundant components of a Protection System to consider are as follows:

1. A single protective relay which responds to electrical quantities used for primary protection;
2. A single communications system, necessary for correct operation of protective functions, which is not monitored or not reported;
3. A single DC supply associated with protective functions that is not monitored for both low voltage and open circuit, with alarms centrally monitored;
4. A single DC Control Circuitry that causes the primary and local backup protection system to not operate properly and triggers remote delayed clearing.

4. Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?

☐ Yes
☒ No

Comments:

The additions which require a Corrective Action Plan for the subset of Table 1 extreme events (footnote 13, 2e-2h) are beyond what is stated in the conclusion of the SPCS and SAMS "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request" report. This report recommended the following:

Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three-phase faults the described component failures of a Protection System[13] that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

Corrective Action Plans for low probability extreme events should not be required. However, it is reasonable that if Cascading is caused by the occurrence of an extreme event, an evaluation of possible actions designed to reduce the likelihood be conducted, as is currently stated in TPL-001-4 for extreme events (R4.5). Based on the conlusion of the above mentioned SPCS and SAMS report, it is understood that the intent should be to clarify that **both** three-phase faults with stuck breaker **and** failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing shall be considered as part of those extreme events in Table 1 that are expected to produce more severe System impacts in accordance with the existing language of TPL-001-4 R4.5. In other words, clarify that the "or" in Table 1 – Extreme Stability Events should not be interpreted as you only need to consider either stuck breaker or relay failure in R4.5. This is accomplished by simply breaking these events apart in Table 1 as shown below (and as in the current TPL-001-5 draft):

2. Local or wide area events affecting the Transmission System such as:
    a. 3Ø fault on generator with stuck breaker[10] resulting in Delayed Fault Clearing.
    b. 3Ø fault on Transmission circuit with stuck breaker[10] resulting in Delayed Fault Clearing.
    c. 3Ø fault on transformer with stuck breaker[10] resulting in Delayed Fault Clearing.
    d. 3Ø fault on bus section with stuck breaker[10] resulting in Delayed Fault Clearing.
    e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
    f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
    g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
    h. 3Ø fault on bus section with failure of a non-redundant comoponent of a Protection System[13] resulting in Delayed Fault Clearing.
    i. 3Ø internal breaker fault.
    j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

To further emphasize this point, refer to the alternatives for addressing reliability risks associated with single points of failure outlined in Charper 2 of the SPCS and SAMS report:

- *Place additional emphasis on assessment of a three-phase fault and protection system failure*
    - *Provideds assurance that areas where a three-phase fault accompanied by a single point of failure that will cause an adverse impact are identified and evaluated*
- *Elevate to a planning event with its own system performance criteria*

- *Probability of three-phase fault with a protection system failure is low enough that it does not warrant a planning event*
- *Keep as an extreme event with no change (other than footnote 13)*
  - *Does not provide assurance a three-phase fault with protection system failure is studied in planning assessments*

From the above language describing the considered alternatives, it can be ascertained that the concern is ensuring that the language in the standard be updated to assure three-phase faults with protection system failure are studied in planning assessments, not that a "subset of Table 1 Extreme Events" be created that are treated differently than other Extreme Events by elevating them to requiring Corrective Action Plans because "the probability of three-phase faults with a protection system failure is low enough that it does not warrant a planning event". Furthermore, there is no technical justification to elevate a three-phase fault with failure of a non-redundant component of a Protection System events above three-phase fault with stuck breaker events.

Although WAPA strongly disagrees with requiring a Corrective Action Plan for this "subset of Table 1 extreme events", if this requirement is carried forward WAPA recommends creating a separate P8 Event for these three-phase failure of a non-redundant component of a Protection System events because it makes Table 1 clearer to read, understand and differentiate between what is required of these events compared to other Extreme Events.

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability (all events): a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. d. Simulate Normal Clearing unless otherwise specified. e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only (P0 through P7 events only)**: f. Applicable Facility Ratings shall not be exceeded. g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. h. Planning event P0 is applicable to steady state only. i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only (P1 through P7 events only):** j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P8 Multiple Contingency *(Fault plus non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6] 5. Bus Section	3Ø	EHV, HV	Yes	Yes

5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))

☒ Yes
☐ No

Comments:

6. Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?

☒ Yes
☐ No

Comments:

7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

☐ Yes
☒ No

Comments:

There is a concern that utilities will not be able to meet the 60 month implementation plan in a reliabile manner. Unlike other potential areas identified in Planning Studies where the system may not meet the System Performance Requirements outlined in Table 1, other temporary reliable solutions, such as the use of Operating Procedures, are available that can be implemented until a long term solution (capital project) is completed. In many instances the only way to fully mitigate impacts resulting from "failure of a non-redundant component of a Protection System" event is to add redundancy. If this cannot be achieved in 60 months utilities may be forced to make undesirable system protection adjustments that could result in a higher rate of misoperations, reduction of system security, and reduced reliability until redundancy can be added. This should not be interpreted as utilities ignoring the importance of adding redundancy at critical points on the system, but implementation should be done on a cost/benefit (risk assessment) basis that takes into consideration the resources individual utilities have to adequately address areas of concerns resulting form single points of failure. In other words, the timing requirement of the implementation plan should not be so prescriptive that it leads to greater reliability risks than the conerns associated with the potential consequences of a single point of failure event.

8. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

☐ Yes
☒ No

Comments:

9. Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?

☒ Yes
☐ No

Comments:

10. Do you have any other general recommendations/considerations for the drafting team?

☒ Yes
☐ No

Comments:

WAPA believes there is risk with the proposed changes of the single point of failure (SPF) language that will not significantly improve reliability. There is likelihood this change may even reduce reliability by having the CAPs force entities to redirect its limited resources away from other important reliability needs to solve SPF identified issue. Further, implementation of the CAPs may likely cause significant mis-ops while system protection systems are being modified to eliminate SPFs thus reducing reliability and increase risk to the transmission system.

Frequency of these SPF events are so seldom, they do not warrant the cost to eliminate unless there are significant risks to the transmission system such as instability and cascading. No data has been provided to demonstrate that SPFs have been a significant factor in system outages.

Table A: Criteria for Buses to be Tested
Buses operated at 200 kV or higher with 4 or more circuits
Buses operated at 100 kV to 200 kV with 6 or more circuits
Buses operated at 100 kV or higher that directly supply off-site power to a nuclear generating station
Any additional buses operated at 100 kV or higher that the Transmission Planner believes are necessary for the reliable operation of the bulk power system

Table C: Performance Measures
1. Loss of synchronism of generating units totaling greater than 2,000 MW or more in the Eastern Interconnection or Western Interconnection, or 1,000 MW or more in the ERCOT or Québec Interconnections
2. Loss of synchronism between two portions of the system
3. Negatively damped oscillations

Consideration of Comments

Project Name: 2015-10 Single Points of Failure | TPL-001-5

Comment Period Start Date: 4/25/2017

Comment Period End Date: 5/24/2017

There were 63 sets of responses, including comments from approximately 180 different people from approximately 129 companies representing 10 of the Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Director of Standards Development, Steve Noess (via email) or at (404) 446-9691.

Questions

1. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?
2. Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?
3. Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?
4. Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?
5. Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))
6. Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?
7. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?
8. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?
9. Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?
10. Do you have any other general recommendations / considerations for the drafting team?

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

SDT Response to Informal Industry Comments

The SDT appreciates the depth of the industry comments and has sought to address each comment submitted during the review of the proposed TPL-001-5 draft Reliability Standard. The SDT has dissected the industry input for each informal comment period question into common themes and seeks to address each here.

Q1	Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that move away from the 6 month duration outage to limited known outages selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) for the time horizon of the operations planning horizon through the near term planning horizon?

In response to Q1, the industry comments ranged from:

- Concerns with "consultation with Reliability Coordinator" text.
- If the RC is required to participate in TPL-001-5, then the RC should be identified as an applicable entity in the TPL standard.
- Outage coordination is an operational issue, not a planning issue.
- IRO-0017 sufficiently covers outage coordination.
- May create additional or duplicate work.
- Consider reducing the 6-month minimum duration for outages that should be considered.
- Need to strengthen the existing Table 1 - P3 and P6 Planning Events to ensure that all outages are accommodated.

Upon reviewing the industry comments, the SDT noted the following considerations of FERC Order 786:

- Planned maintenance outages less than six months may result in impacts during peak and off-peak periods;
- Planned outages during those times should be considered to allow for a single element to be taken out of service without compromising the ability to meet demand;
- Criticality of elements taken out for maintenance could result in N-1 outage and loss of non-consequential load or impact to reliability;

- Planned outages are not “hypothetical outages” and should not be treated as multiple contingencies in the planning standard (should be addressed in N-0 base case);
- Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages;
- The Near-Term Transmission Planning Horizon requires annual assessments using Year one or year two, and year five, and known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon.

The SDT considered the wide range of industry comments received as well as the NERC System Analysis and Modeling Subcommittee (SAMS) report to the NERC Planning Committee (that was also vetted through the industry) and believes the most cost-effective means to address the intent of the NERC directives in FERC Order 786 is to use IRO -017-1 as the vehicle to assure that all types of known scheduled outages are being reviewed and coordinated to mitigate potential reliability impacts. The NERC SAMS recommended that IRO-017-1 should be used to assure that all types of known scheduled outages are being reviewed and coordinated, as well as used to direct actions that must be taken, to mitigate reliability impact (“FERC Order 786 Directives” - NERC SAMS White Paper, July 2016, pg. 3). As directed by FERC Order 786 (Para 40) and consistent with the NERC SAMS recommendation, the TPL-001-5 Requirement R1.1.2 is modified by removing the six month duration criterion. SAMS also recommended that language be added to R1.1.2 referencing the outage coordination process developed in IRO-017-1 Requirement R1. The drafting team believes that requiring consultation with the Reliability Coordinator when the Planning Coordinator and Transmission Planner maintain System models that represent known outages is consistent with IRO-017-1 Requirement R1, as well as Requirement R4 which requires the Planning Coordinator and Transmission Planner to jointly develop solutions with its respective Reliability Coordinator(s) for identified issues or conflicts with planned outages in its Planning Assessment for the Near-Term Transmission Planning Horizon. In this way, IRO-017-1 R1 requires the Reliability Coordinator to identify outages and TPL-001-5 R1.1.2 requires the Planning Coordinator and Transmission Planner to consult with the Reliability Coordinator on which known outages to represent in System models for the Near-Term Planning Horizon (the transmission planning period that covers Year One through five).

The term consultation was used in Requirement R1.1.2 to specify that the Reliability Coordinator does not direct which known outages shall be represented in the System models maintained by the Planning Coordinator and Transmission Planner. Instead, the Planning Coordinator and Transmission Planner consult with the Reliability Coordinator to obtain additional information beyond simply what outages are scheduled in outage coordination systems (e.g. CROW, NERC SDX, etc.). The additional information that the Reliability Coordinator can provide to aid the Planning Coordinator and Transmission Planner when selecting known outages to represent may include: the likelihood of the known outage occurring (e.g., outages are not hypothetical, consistent with FERC Order 786, Paragraph 42), the potential for known outages to be concurrent (e.g., situations when Table 1 Category P3 and P6 events are not sufficient to represent System conditions, consistent with FERC Order 786, Paragraph 44), or expected known outage duration (e.g. situations when outages may extend from the Operations Horizon into the Near-Term Planning Horizon; situations when outages span multiple seasons or peak and off-peak periods, consistent with FERC Order 786, Paragraph 41). It is noted that the term consultation has been used elsewhere in the Reliability Standards (e.g. PRC-023-4, VAR-001-4.1) to indicate that other entities may have valuable information necessary for consideration, but where it may be inappropriate for those entities to direct decision-making.

To address outage coordination the SDT is initiating a SAR to enhance IRO-017 to include known outages in the Near-Term Planning Horizon. The specific language will be developed subsequent to an IRO-017 SAR and SDT. The SAR will include the objective to use the coordination process developed pursuant to IRO-017-1 Requirement R1 to direct how all known scheduled outages are reviewed and the actions that must be taken. The following objectives should be added to IRO-017-1 Requirement R1:

- Describe how the review of known scheduled outages by the RC, PC, TO, and TP will be integrated into the Near Term Assessment of the Planning Horizon required by TPL-001-4, and whether and which of these known scheduled outages will be studied in this Assessment.
- Describe how emerging challenges and the inability to schedule outages will be communicated from the TO and RC to the TP and PC to be addressed in a future Corrective Action Plan pursuant to TPL-001-4.

The TPL SDT believes that modifying R1 in such as way offers win-win collaboration between the Reliability Coordinator and the planning entities. The communication process developed in accordance with IRO-017 to meet the above objectives will provide the opportunity for an RC to forward outages that have been scheduled in the near term planning horizon to the Planning Coordinator for analysis as well as providing the opportunity for the Reliability Coordinator to make the Planning Coordinator aware of other operational issues that may be developing. The Planning Coordinator will gain additional situational awareness from the Reliability Coordinator perspective as well as gaining insight on issues for possible inclusion in the Near-Term Planning Horizon.

Q2	Do you agree with the proposed changes to Requirement 2, Part 2.4.5 which addresses the Federal Energy Regulatory Commission (FERC) order to add the spare equipment with long lead time to the dynamics analysis?

The SDT considered the industry comments regarding Question 2 and maintained the proposed TPL-001-5 language that addresses FERC Order 786 Paragraph 89.

Q3	Do you agree with the further clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events?

The SDT paid considerable attention to the depth of the industry comments received regarding Question 3 and has sought to address general and specific industry comments with the following response. If one theme, more than any other, was communicated by industry it was to desire specificity about the Protection System components that must be redundant. The SDT seeks to make clear that the draft Footnote 13, as well as changes to the P5 and extreme events, do not prescribe any level of redundancy. Instead, the changes proposed by the SDT prescribe that SPF in a limited set of non-redundant Protection System components must be considered when assessing system performance given the P5 and extreme events. The performance requirements of TPL-001-5 remain unchanged; the changes to Footnote 13 are intended to improve assessments of existing or planned System equipment that may harbor risks to reliability.

Industry comment: The expansion of components that must be considered when evaluating redundancy will cause industry to perform many more studies, expand equipment monitoring programs, and install redundant equipment. These actions are unwarranted because of the low probability of failure of these non-redundant components.

SDT rationale: The industry has been aware of concerns about Protection System component single point-of-failure (SPF) and corresponding risks to the BES since as early as the March 30, 2009 NERC Alert. The draft TPL-001-5 language proposed by the SDT is consistent with how other identified risks to reliability are incorporated into the Transmission System Planning standard, including similar assessment of low probability events (e.g., breaker failure). The changes to Footnote 13 do not prescribe any level of redundancy. On the contrary, what the SDT has proposed in TPL-001-5 is to specify which non-redundant components of a Protection System must be considered when assessing whether a failure will lead to Delayed Clearing. The purpose of proper simulation of the Planning and Extreme events of TPL-001-5 Table 1 is to ensure the System meets performance requirements. The SDT intends for the accuracy of those simulations to be enhanced by “raising the bar” on SPF.

Industry comment: The Protection System components included in Footnote 13 are unclear, require additional clarity, and should be more prescriptive.

SDT rationale: The SDT agrees with the industry comments. Upon the first release of the proposed TPL-001-5, the SDT desired to maintain the components considered in Footnote 13 as general as possible, while still adhering to the NERC Glossary of Terms definition of Protection System. However, the SDT acknowledges that more specificity within Footnote 13 will better align with the SPCS/SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request" and limit the scope of Protection System components considered for non-redundancy. The proposed revised language is incorporated into the revised proposed TPL-001-5.

Industry comment: The rationale section for the Table 1 P5 event and Footnote 13 should be revised.

SDT rationale: The SDT agrees with the comment and made changes to the rational section, as follows.

<u>Revised Paragraph 1:</u> The revisions to Table 1 Category P5 event require an entity to model a single point of failure of a non-redundant Protection System component that will result in Delayed Fault Clearing. The evaluation shall address all Protection Systems affected by the failed component and the increases (if any) of the total fault clearing time. Footnote 13 provides the attributes of the specific system component failure that the entity shall consider for evaluation.

<u>Revised Paragraph 5:</u> [Footnote 13, Part 1] The drafting team sought to limit the scope of protective relays considered non-redundant components of a Protection System in the following ways:

1. May experience a single point of failure.
2. Respond to electrical quantities. Relays that do not respond to electrical quantities, e.g. sudden pressure, are always used in conjunction with relays that respond to electrical quantities and may offer some redundancy.
3. Are necessary for high-speed or Normal Clearing. Given that typical Protection System designs implement primary protection at the local terminal for Normal Clearing and backup protective relaying locally and remotely for Delayed Clearing, the drafting team did not include backup protective relays or overlapping zonal protection as components of a Protection System specified in footnote 13.

<u>Revised Paragraph 6:</u> [Footnote 13, Part 3] Given the increasing importance of communication-aided Protection Systems (e.g., pilot protection schemes, direct transfer tripping schemes, permissive transfer tripping schemes, etc.), the proper operation of the communication system must be considered when considering potential SPF components of Protection Systems. Although the SAMS/SPCS report noted that a SPF in a communication system posed a lower level of risk, the drafting team augmented the SAMS/SPCS recommendations to include reference to the subset of communication systems that are part of a communication-aided Protection System, necessary where the performance of that

Protection System is required to achieve Transmission System Planning Performance Requirements, enumerated in Table 1 of TPL-001-5. In other words, a communication-aided Protection System that may experience a SPF, causing it to operate improperly or not at all leading to Delayed Clearing, must be considered as part of non-redundancy. The drafting team concluded that the failure of communication-aided Protection Systems may take many forms; however, by alarming and monitoring these systems, the overall risk of impact to the Bulk Electric System is reduced to an acceptable level. Most new Protection Systems deployed in the industry include communication-aided protection with component and communication failure alarms monitored at centralized Control Centers. This alarm monitoring is similar to the requirement associated with station DC supplies. Therefore, this requirement is more applicable to legacy systems that need communication-aided Protection Systems to meet performance requirements of the TPL-001-5 standard.

Industry comment: Are Protection System components that protect non-BES equipment connected to the BES buses included in Footnote 13?

SDT rationale: The TPL-001-5 standard establishes Transmission system planning performance requirements whereby each Transmission Planner and Planning Coordinator prepares an annual Planning Assessment of its portion of the BES. The TPL-001-5 Table 1 prescribes the System performance requirements applicable to Facilities given planning and extreme events. By proposing changes to Footnote 13, the SDT prescribes which non-redundant components of a Protection System must be considered for SPF. The failure of a non-redundant component of a Protection System may lead to Delayed Clearing given a fault located on the BES or on non-BES equipment, and should be appropriately simulated.

Industry comment: Single Protection System components of Footnote 13 should be clarified to mean only those single Protection System components that isolate the fault being studied.

SDT rationale: The SDT disagrees with the need to clarify that non-redundant Protection System components must be associated with clearing the fault. The SDT intention is to ensure failure of a non-redundant Protection System component that leads to Delayed Clearing be properly assessed. A non-redundant Protection System component that does not participate in the Normal Clearing of a fault, cannot cause Delayed Clearing if it fails.

Industry comment: Are Protection System components that protect non-BES equipment connected to the BES buses included in Footnote 13?

SDT rationale: The TPL-001-5 standard establishes Transmission system planning performance requirements whereby each Transmission Planner and Planning Coordinator prepares an annual Planning Assessment of its portion of the BES. The TPL-001-5 Table 1 prescribes the

System performance requirements applicable to Facilities given planning and extreme events. By proposing changes to Footnote 13, the SDT prescribes which non-redundant components of a Protection System must be considered for SPF. The failure of a non-redundant component of a Protection System may lead to Delayed Clearing given a fault located on the BES or on non-BES equipment, and should be appropriately simulated.

Industry comment: Single Protection System components of Footnote 13 should be clarified to mean only those single Protection System components that isolate the fault being studied.

SDT rationale: The SDT disagrees with the need to clarify that non-redundant Protection System components must be associated with clearing the fault. The SDT intention is to ensure failure of a non-redundant Protection System component that leads to Delayed Clearing be properly assessed. A non-redundant Protection System component that does not participate in the Normal Clearing of a fault, cannot cause Delayed Clearing if it fails.

Industry comment: The parenthetical portion of the TPL-001-4 Footnote 13 that specifies which relay types are considered should not be removed in the proposed TPL-001-5 Footnote 13.

SDT rationale: [Footnote 13, Part 1] The SDT disagrees with the comment, primarily because all relay types responding to electrical quantities used for primary protection (Normal Clearing) are included in the TPL-001-4 Footnote 13. In other words, the SDT believes that removing the specific relay types allows the applicable entity to consider whether single protective relays may be non-redundant and, if failed, would lead to Delayed Clearing.

Industry comment: A communication system was not part of the Standards Authorization Request as one of the non-redundant components of a Protection System to consider for inclusion in Footnote 13.

SDT rationale: [Footnote 13, Part 2] Consistent with the direction in the SAR, the SDT considered the recommendations for modifying TPL-001-4 as identified in the SPCS/SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request". As part of that consideration, the SDT thoroughly reviewed the methodology as well as the findings of the report, such as "a single point of failure in a communication system poses a lower level of risk". However, the SAMS/SPCS report "only analyzed communication equipment in protection systems where communication-aided protection is needed to satisfy the system performance required in NERC Reliability Standards." The SDT believed that this report assumption necessitated that communications be included in the potential non-redundant components of a Protection System considered in Footnote 13 for two reasons. First, the system performance required, referred to as Performance Measure in the Order 754 data request, was loss of synchronism and/or negatively damped oscillations. This performance requirement is significantly different than the performance requirements of Planning Events of TPL-001-4 Table 1. Second, the SAMS/SPCS report acknowledged that: “the risk associated with a given protection system is dependent on the protection system design. Depending on the protection system design, a single point of failure may result in a failure of the communication-aided system to initiate a high-speed trip (e.g., a permissive overreaching transfer trip scheme), in which case delayed tripping will occur.” The SDT believed that evaluating redundancy of Protection System components is integral to properly assessing system performance for the P5 and applicable extreme events; therefore, without presuming Protection System design, the non-redundant communication system must be included in Footnote 13. Additionally, the SAMS/SPCS report stated that communication systems “are typically monitored and alarmed via SCADA or tested periodically”, further mitigating the risk of single point-of-failure. The SDT adapted this SAMS/SPCS finding to limit the communication systems to be considered as part of Footnote 13 to those which are not monitored or not reported.

Industry comment: The reference to single DC supply associated with protective functions in Footnote 13 is not specific enough, e.g. battery health.

SDT rationale: [Footnote 13, Part 3] The SDT intended single DC supply to refer to the entire set of equipment that comprises the DC source supplying power to Protection System components necessary for Normal Clearing. In other words, the SDT sought to specify that, within the entire set of equipment comprising the single DC supply, a failure of a piece of equipment that causes the single DC supply to be unable to source power to the protective functions necessary for Normal Clearing must be considered as part of Footnote 13. Relatedly, the SDT agrees that a typical station battery bank is only one part of the single DC supply. Further, a failure of a station battery may be masked for short time by the AC-sourced station battery charger. However, the SDT did not prescribe specific DC supply design configurations. Instead, the SDT emphasized that the single DC supply must be considered for susceptibility to SPF as part of Footnote 13.

Industry comment: It is unclear whether Footnote 13, Item 4 intends for trip coils to be redundant.

SDT rationale: [Footnote 13, Part 4] The SDT intends for trip coils to be considered as part of non-redundant components of a Protection System that may be SPF. It is clear that, given a failure of a single trip coil without a second (e.g., parallel) trip coil, a fault necessitating the opening of the breaker commanded by the unary trip coil will not occur, leading to Delayed Clearing. The SDT does not intend to prescribe whether redundant trip coils are required; instead the SDT has proposed language that requires that non-redundant DC control circuit components, such as trip coils, be considered as part of Footnote 13. The SDT does note that, in most instances, a fault and a failure of a non-redundant trip coil may lead to breaker failure initiation, resulting in Delayed Clearing.

Industry comment: [Footnote 13, Part 4] DC control circuitry should be allowed similar monitoring provisions as with the other parts of Footnote 13.

SDT rationale: The SDT disagrees with the industry comment. While trip coil monitoring devices are commonly available to give awareness of potential trip coil failure, the SDT believes monitoring trip coil failure or relay trouble indication is insufficient to ensure that a SPF is not present within a single control circuit. Similarly, DC undervoltage relaying or other control circuit continuity monitoring may indicate a problem with part of the DC control circuit, but may not give awareness of SPF risks such as serial tripping devices (ANSI #86 and #94 devices). Therefore, The SDT did not incorporate a monitoring provision into Footnote 13, Part 4 and intends for non-redundant components within the DC control circuitry of a Protection System to be considered as part of Footnote 13.

Q4	Do you agree with the proposed Requirement 4, Part 4.6 additions which require a Corrective Action Plan for this subset of Table 1 extreme events (footnote 13, 2e-2h)?

The SDT recognized that the industry comments received regarding Question 4 were particularly negative. The SDT would like to address the most common comment received: requiring Corrective Action Plans as part of Requirement R4.6 goes beyond the scope of the SAR, was not part of the recommendations from the SPCS/SAMS report titled "Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request", and/or is not justifiable given the low likelihood of occurrence. With regards to industry commenters, approximately two-thirds of respondents expressed this concern. The SDT acknowledges this comment and appreciates the majority of industry feedback. While it is clear that a SPF for a Protection System component may lead to significantly longer Delayed Clearing and notably worse system response than typically analyzed breaker failure conditions, the industry has indicated that the probability of simultaneous SPF occurrence with a bolted three-phase fault is low. Therefore the SDT has restored the assessment of SPF for a Protection System component with a three-phase fault to language consistent with TPL-001-4 Requirement 4.5.

The SPF for a Protection System component is an important topic that, the SDT believes, may involve risks that are underappreciated. The SDT considered using Corrective Action Plan changes in proposed Requirement 4.6 or a new Table 1 Planning Events Category P8 to emphasize the importance of this issue, but given the industry comments and lack of a FERC directive did not “raise the bar” at this time. The SDT would like to document an important considerations it considered, that the fault conditions and system performance requirement, referred to as Performance Measure, of the Order 754 data request were very similar to those of Extreme Events of TPL-001-4 Table 1, namely three-phase fault application and conditions that can indicate Cascading. The primary conclusive finding of the SPCS/SAMS report was: “analysis of the data demonstrates the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.” Further, the SPCS/SAMS report concluded that: “additional emphasis in planning studies should be placed on assessment of three-phase faults involving protection system single points of failure.” Despite the SPCS/SAMS report stopping short of recommending that a Corrective Action Plan be developed when analysis concludes Cascading is caused by the occurrence of a three-phase fault and a failure of a non-redundant Protection System component extreme event, the SDT considered this recommendation consistent with the SAR. However, lacking FERC directive, the SDT determined that the existing TPL-001-4 Requirement R4.5 to evaluate possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the SPF event was sufficient given the risk to reliability. However, Planning Coordinators and Transmission Planners should be aware of some important analytical considerations:

1. Breaker failure Delayed Clearing times are typically 7-14 cycles. This may be significantly shorter than the Delayed Clearing times experienced given a failure of a non-redundant Protection System component.
2. Cascading is significantly less likely to occur given breaker failure clearing times. However, the Delayed Clearing times experienced for three-phase fault and a failure of a non-redundant Protection System component could induce Cascading.
3. Experience has shown a single line-to-ground fault that remains un-cleared for a prolonged period may migrate into multiple phases. Therefore, while a single line-to-ground fault, that would otherwise be cleared, may rapidly become a three-phase fault before Delayed Clearing resulting from a failure of a non-redundant Protection System component.
4. Once assessed, demonstrating Cascading given the identified risk of a three-phase fault and a failure of a non-redundant Protection System component, the impacts to System reliability warrant mitigating plans, encompassed by a Corrective Action Plan.

Q5	Do you agree with the drafting team's approach which doesn't add additional applicable entities to the applicability of the standard? (e.g. RC, Transmission Operator (TO), Generator Operator (GO), Distribution Provider (DP))

The most prevalent industry comment regarding applicability was tied to maintenance outages considered in the Planning Assessment for the Near-term Planning Horizon. The industry comments indicated that the Reliability Coordinator should be added as a TPL-001-5 applicable entity. The second-most common industry comment was to not change the TPL requirements as proposed, but instrad IRO-017-1 should be modified to keep maintenance outage coordination within one standard, leaving the TPL-001-5 as a planning standard. Other prominent industry comments included: the Generator Owner and Transmission Owner should be added as applicable entities due to changes to "components" of Protection Systems; and, the Transmission Operator should be added, along with the Reliability Coordinator, given the inclusion of maintenance outages.

Given the challenges of requirements that span multiple Reliability Standards and the corresponding applicability concerns, the SDT has initiated the process to revise the existing SAR as well as propose a new SAR to enhance IRO-017 as the vehicle to identify and communicate known outages for the Near-Term Planning Horizon.

Q6	Do you agree with the 36 month implementation period to address All Requirements except for Requirement R4, Part 4.6, and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4, as well as the definitions?

The SDT considered the industry comments regarding Question 6 and maintained the proposed TPL-001-5 implementation plan.

Q7	Do you agree with the 60 month implementation plan for Requirement 4, Part 4.6 and Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4?

The SDT considered the industry comments regarding Question 7 and maintained the proposed TPL-001-5 implementation plan.

Q8	Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

Given the preponderance of industry comments regarding conflicts between IRO-17-1 and the proposed TPL-001-5, the SDT has initiated the process to revise the SAR, as well as propose a new SAR. Similarly, the SDT has removed the proposed Corrective Action Plan in Requirement R4.6 and maintained the existing TPL-001-4 Requirement R4.5.

The SDT would like to address the specific industry comment: due to the changes incorporated in this proposed TPL standard, Reliability Standard CIP-014-2 – Physical Security can be impacted with the outcome. The SDT understands that CIP-014 Requirement R4 Part 4.1.1.3 applies to Transmission Facilities at a single station or substation location that are identified by its Reliability Coordinator, Planning Coordinator, or Transmission Planner as critical to the derivation of Interconnection Reliability Operating Limits (IROLs) and their associated contingencies. Depending upon the IROL methodologies defined in FAC-014-2, the proposed TPL-001-5 can result in a different scenario for applicable Transmission Facilities for CIP-014-2. However, the SDT believes there is no conflict between CIP-014-2 and the proposed TIP-001-5.

Q9	Do you agree with the teams proposed changes to align the VRF/VSLs for Requirement 4, Part 4.6 with the VRF/VSLs for Requirement 2, Part 2.7?

The SDT believes that the majority of industry comments regarding Question 9 are resolved with the removal of the Corrective Action Plan in Requirement R4.6.

Q10	Do you have any other general recommendations/considerations for the drafting team?

Given the significant changes that the SDT have made to the proposed TPL-001-5 subsequent to the first informal industry comment period, the SDT believes that it has addressed the industry recommendations with regards to topics covered in the Project 2015-10 SAR submitted in response to Question 10.

The SDT would like to address the specific industry comment: when providing additional clarity/rationale on the subject of redundancy, the drafting team consider referring to a technical paper developed by the System Protection Control Task Force developed in 2008 titled: "Protection System Reliability: Redundancy of Protection System Elements". The SDT has considered the technical paper developed in 2008. It is noted that the SDT has proposed the draft footnote 13 and changes to P5 such that it does not prescribe redundancy. Instead, the changes proposed by the SDT prescribe that SPF in a limited set of non-redundant Protection System components must be considered when assessing system performance given the P5 and extreme events.

Additionally, the SDT would like to address the specific industry: the proposed implementation plan makes reference to, in certain circumstances, carrying over from TPL-001-4 the 84-month exception (our word) period related to Corrective Action Plans including Non-Consequential Load Loss and curtailment of Firm Transmission Service, which is unclear. The SDT has proposed the 36-month implementation period to provide sufficient time for PCs and TP to update their annual assessment to include the new System models and studies required by the TPL-001-5. The additional 24-month CAP drafting period is to identify appropriate CAP related to SPF. The 84-month exception period related to CAP including Non-Consequential Load Loss and curtailment of Firm Transmission Service in TPL-001-4 was kept in the TPL-001-5 implementation plan so that the 84-months will not get inadvertently truncated.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the first draft of the proposed standard.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	October 29, 2015
SAR posted for comment	May 26 – June 24, 2016
Informal Comment Period	April 25 – May 24, 2017

Anticipated Actions	Date
45-day formal comment period with initial ballot	September 2017
45-day formal comment period with additional ballot	November 2017
10-day final ballot	February 2018
Board adoption	May 2018

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None.

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**

2. **Number:** **TPL-001-5**

3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

4. **Applicability:**

   4.1. Functional Entity

   4.1.1. Planning Coordinator.

   4.1.2. Transmission Planner.

5. **Effective Date: See Implementation Plan.**

B. Requirements and Measures

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the -MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities.

1.1.2. Known outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

1.1.3. New planned Facilities and changes to existing Facilities.

1.1.4. Real and reactive Load forecasts.

1.1.5. Known commitments for Firm Transmission Service and Interchange.

1.1.6. Resources (supply or demand side) required for Load.

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with MOD-032 including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.1.4. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response:

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. The analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.4.4. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.

- Generation additions, retirements, or other dispatch scenarios.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or Remedial Action Scheme.
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5.

3.3. Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a Remedial Action Scheme is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.2.1. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation.

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall:

4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

4.3.1.1. Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2. Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3. Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

C. Compliance

1. **Compliance Monitoring Process**

   1.1. **Compliance Enforcement Authority:** "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

   1.2. **Evidence Retention:** The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit

   The applicable entity shall keep data identified in Measures M1 through M8 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

   - Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

   1.3. **Compliance Monitoring and Enforcement Program** As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

   1.4. **Compliance Monitoring Period and Reset Timeframe:**

   Not applicable.

   1.5. **Compliance Monitoring and Enforcement Processes:**

   - Compliance Audits
   - Self-Certifications
   - Spot Checks
   - Compliance Violation Investigations
   - Self-Report
   - Complaints

   1.6. **Additional Compliance Information:**

   None.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R1.	The responsible entity's System model failed to represent one of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent two of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent three of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, Parts 1.1.1 through 1.1.6. OR The responsible entity's System model did not represent projected System conditions as described in Requirement R1. OR The responsible entity's System model did not use data consistent with that provided in accordance with the MOD-032 standards and other sources, including items represented in the Corrective Action Plan.
R2.	The responsible entity failed to comply with Requirement R2, Part 2.6.	The responsible entity failed to comply with Requirement R2, Part 2.3 or Part 2.8.	The responsible entity failed to comply with one of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, Part 2.5, or Part 2.7.	The responsible entity failed to comply with two or more of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, or Part 2.7. OR The responsible entity does not have a completed annual Planning Assessment.

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R3.	The responsible entity did not identify planning events as described in Requirement R3, Part 3.4 or extreme events as described in Requirement R3, Part 3.5.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for one of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R3, Part 3.2 to assess the impact of extreme events.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for two of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R3, Part 3.3.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for three or more of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies to determine that the BES meets the performance requirements for the P0 or P1 categories in Table 1. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R4.	The responsible entity did not identify planning events as described in Requirement R4, Part 4.4 or extreme events as described in Requirement R4, Part 4.5.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for one of the categories (P1 through P7) in Table 1. OR	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for two of the categories (P1 through P7) in Table 1. OR	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for three or more of the categories (P1 through P7) in Table 1. OR

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
		The responsible entity did not perform studies as specified in Requirement R4, Part 4.2 to assess the impact of extreme events.	The responsible entity did not perform Contingency analysis as described in Requirement R4, Part 4.3.	The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R5.	N/A	N/A	N/A	The responsible entity does not have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, or the transient voltage response for its System.
R6.	N/A	N/A	N/A	The responsible entity failed to define and document the criteria or methodology for System instability used within its analysis as described in Requirement R6.
R7.	N/A	N/A	N/A	The Planning Coordinator, in conjunction with each of its Transmission Planners, failed to determine and identify individual or joint responsibilities for performing required studies.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
0	February 8, 2005	BOT Approval	Revised
0	June 3, 2005	Fixed reference in M1 to read TPL-001-0 R2.1 and TPL-001-0 R2.2	Errata
0	July 24, 2007	Corrected reference in M1. to read TPL-001-0 R1 and TPL-001-0 R2.	Errata
0.1	October 29, 2008	BOT adopted errata changes; updated version number to "0.1"	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote 'b' pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC	

Version	Date	Action	Change Tracking
		has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-3 was created after the Board of Trustees approved the revised footnote 'b' in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	TBD	Adopted by the NERC Board of Trustees.	Revised To address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability: a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. d. Simulate Normal Clearing unless otherwise specified. e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only**: f. Applicable Facility Ratings shall not be exceeded. g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. h. Planning event P0 is applicable to steady state only. i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only:** j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P0 No Contingency	Normal System	None	N/A	EHV, HV	No	No
P1 Single Contingency	Normal System	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single Pole of a DC line	SLG			
P2 Single Contingency	Normal System	1. Opening of a line section w/o a fault [7]	N/A	EHV, HV	No[9]	No[12]
		2. Bus Section Fault	SLG	EHV	No[9]	No
				HV	Yes	Yes
		3. Internal Breaker Fault [8] (non-Bus-tie Breaker)	SLG	EHV	No[9]	No
				HV	Yes	Yes
		4. Internal Breaker Fault (Bus-tie Breaker) [8]	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P3 Multiple Contingency	Loss of generator unit followed by System adjustments[9]	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single pole of a DC line	SLG			
P4 Multiple Contingency *(Fault plus stuck breaker[10])*	Normal System	Loss of multiple elements caused by a stuck breaker [10](non-Bus-tie Breaker) attempting to clear a Fault on one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
		6. Loss of multiple elements caused by a stuck breaker[10] (Bus-tie Breaker) attempting to clear a Fault on the associated bus	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P5 Multiple Contingency *(Fault plus non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
P6 Multiple Contingency *(Two overlapping singles)*	Loss of one of the following followed by System adjustments.[9] 1. Transmission Circuit 2. Transformer [5] 3. Shunt Device[6] 4. Single pole of a DC line	Loss of one of the following: 1. Transmission Circuit 2. Transformer [5] 3. Shunt Device [6]	3Ø	EHV, HV	Yes	Yes
		4. Single pole of a DC line	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P7 Multiple Contingency *(Common Structure)*	Normal System	The loss of: 1. Any two adjacent (vertically or horizontally) circuits on common structure [11] 2. Loss of a bipolar DC line	SLG	EHV, HV	Yes	Yes

<table>
<tr><th colspan="2">Table 1 – Steady State & Stability Performance Extreme Events</th></tr>
<tr><td colspan="2">Steady State & Stability
For all extreme events evaluated:
a. Simulate the removal of all elements that Protection Systems and automatic controls are expected to disconnect for each Contingency.
b. Simulate Normal Clearing unless otherwise specified.</td></tr>
<tr><td>Steady State
1. Loss of a single generator, Transmission Circuit, single pole of a DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, single pole of a different DC Line, shunt device, or transformer forced out of service prior to System adjustments.
2. Local area events affecting the Transmission System such as:
a. Loss of a tower line with three or more circuits.[11]
b. Loss of all Transmission lines on a common Right-of-Way[11].
c. Loss of a switching station or substation (loss of one voltage level plus transformers).
d. Loss of all generating units at a generating station.
e. Loss of a large Load or major Load center.
3. Wide area events affecting the Transmission System based on System topology such as:
a. Loss of two generating stations resulting from conditions such as:
i. Loss of a large gas pipeline into a region or multiple regions that have significant gas-fired generation.</td><td>Stability
1. With an initial condition of a single generator, Transmission circuit, single pole of a DC line, shunt device, or transformer forced out of service, apply a 3Ø fault on another single generator, Transmission circuit, single pole of a different DC line, shunt device, or transformer prior to System adjustments.
2. Local or wide area events affecting the Transmission System such as:
a. 3Ø fault on generator with stuck breaker[10] resulting in Delayed Fault Clearing.
b. 3Ø fault on Transmission circuit with stuck breaker[10] resulting in Delayed Fault Clearing.
c. 3Ø fault on transformer with stuck breaker[10] resulting in Delayed Fault Clearing.
d. 3Ø fault on bus section with stuck breaker[10] resulting in Delayed Fault Clearing.
e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.</td></tr>
</table>

ii. Loss of the use of a large body of water as the cooling source for generation. iii. Wildfires. iv. Severe weather, e.g., hurricanes, tornadoes, etc. v. A successful cyber attack. vi. Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. i. 3Ø internal breaker fault. j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss.
2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria.
3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss.
4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service.
5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers.
6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground.
7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point.
8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker.
9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered.

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing. 11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less. 12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction. 13. For purposes of this standard, non-redundant components of a Protection System to consider are as follows: 1. A single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying; 2. A single communications system, necessary for correct operation of a communication-aid protection scheme required for Normal Clearing, which is not monitored or not reported; 3. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit; 4. A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. The process must include the following:

1. Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues
2. Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:
    a. Date, time, and location for the meeting
    b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
    c. Provisions for a stakeholder comment period
3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
    a. System Load level and estimated annual hours of exposure at or above that Load level
    b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency
2. Amount of Non-Consequential Load Loss with:
    a. The estimated number and type of customers affected

   b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community
3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance
4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance
5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12
6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12
7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12
8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

<u>III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required</u>

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

1. The voltage level of the Contingency is greater than 300 kV
   a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or
   b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)
2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the first draft of the proposed standard.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	October 29, 2015
SAR posted for comment	May 26 – June 24, 2016
Informal Comment Period	April 25 – May 24, 2017

Anticipated Actions	Date
45-day formal comment period with initial ballot	September 2017
45-day formal comment period with additional ballot	November 2017
10-day final ballot	February 2018
Board adoption	May 2018

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None.

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**

2. **Number:** **TPL-001-~~4~~5**

3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

4. **Applicability:**

   4.1. Functional Entity

   4.1.1. Planning Coordinator.

   4.1.2. Transmission Planner.

~~**5. Effective Date:** Requirements R1 and R7 as well as the definitions shall become effective on the first day of the first calendar quarter, 12 months after applicable regulatory approval. In those jurisdictions where regulatory approval is not required, Requirements R1 and R7 become effective on the first day of the first calendar quarter, 12 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.~~

~~Except as indicated below, Requirements R2 through R6 and Requirement R8 shall become effective on the first day of the first calendar quarter, 24 months after applicable regulatory approval. In those jurisdictions where regulatory approval is not required, all requirements, except as noted below, go into effect on the first day of the first calendar quarter, 24 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities.~~

~~For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-4, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-4:~~

- ~~P1-2 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)~~
- ~~P1-3 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)~~
- ~~P2-1~~
- ~~P2-2 (above 300 kV)~~
- ~~P2-3 (above 300 kV)~~
- ~~P3-1 through P3-5~~

- ~~P4-1 through P4-5 (above 300 kV)~~
- ~~P5 (above 300 kV)~~

5. ~~Requirements~~**Effective Date: See Implementation Plan.**

B. Requirements and Measures

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the ~~MOD-010 and MOD-012 standards~~MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities.

1.1.2. Known outage(s) of generation or Transmission Facility(ies) ~~with a duration of at least six months.~~as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

1.1.3. New planned Facilities and changes to existing Facilities.

1.1.4. Real and reactive Load forecasts.

1.1.5. Known commitments for Firm Transmission Service and Interchange.

1.1.6. Resources (supply or demand side) required for Load.

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with ~~MOD-010 and MOD-012, MOD-032~~ MOD-032 including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short

circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.1.4. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response~~-~~:

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be ~~studied~~assessed. The ~~studies~~analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

~~2.4.3.~~2.4.4. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

~~2.4.4.~~2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or ~~Special Protection Systems~~ Remedial Action Scheme.

- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5.

3.3. Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. ~~3.3.1.1.~~ Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. ~~3.3.1.2.~~ Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a ~~Special Protection System~~Remedial Action Scheme is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.2.1. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation.

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall~~-~~:

4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

4.3.1.1. ~~4.3.1.1.~~ Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

4.3.1.2. ~~4.3.1.2.~~ Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

4.3.1.3. ~~4.3.1.3.~~ Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

~~B.~~C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit

The ~~1.1 Compliance Enforcement Authority~~

~~Regional Entity~~ applicable entity shall keep data identified in Measures M1 through M8 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

1.3. Compliance Monitoring and Enforcement Program As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

~~1.2~~ **Compliance Monitoring Period and Reset Timeframe**

1.4. :

Not applicable.

1.5. Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checks
- Compliance Violation Investigations
- Self-Report
- Complaints

~~1.3~~ **Additional Compliance Information**

1.6. :

None~~-~~.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	The responsible entity's System model failed to represent one of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent two of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent three of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, Parts 1.1.1 through 1.1.6. OR The responsible entity's System model did not represent projected System conditions as described in Requirement R1. OR The responsible entity's System model did not use data consistent with that provided in accordance with the ~~MOD-010 and MOD-012~~ MOD-032 standards and other sources, including items represented in the Corrective Action Plan.
R2.	The responsible entity failed to comply with Requirement R2, Part 2.6.	The responsible entity failed to comply with Requirement R2, Part 2.3 or Part 2.8.	The responsible entity failed to comply with one of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, Part 2.5, or Part 2.7.	The responsible entity failed to comply with two or more of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, or Part 2.7. OR The responsible entity does not have a completed annual Planning Assessment.

R #	Violation Severity Levels			
	Lower VSL	**Moderate VSL**	**High VSL**	**Severe VSL**
R3.	The responsible entity did not identify planning events as described in Requirement R3, Part 3.4 or extreme events as described in Requirement R3, Part 3.5.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for one of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R3, Part 3.2 to assess the impact of extreme events.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for two of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R3, Part 3.3.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for three or more of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies to determine that the BES meets the performance requirements for the P0 or P1 categories in Table 1. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R4.	The responsible entity did not identify planning events as described in Requirement R4, Part 4.4 or extreme events as described in Requirement R4, Part 4.5.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for one of the categories (P1 through P7) in Table 1. OR	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for two of the categories (P1 through P7) in Table 1. OR	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for three or more of the categories (P1 through P7) in Table 1. OR

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
		The responsible entity did not perform studies as specified in Requirement R4, Part 4.2 to assess the impact of extreme events.	The responsible entity did not perform Contingency analysis as described in Requirement R4, Part 4.3. ~~OR~~ ~~The responsible entity did not develop a Corrective Action Plan as described in Requirement R4, Part 4.6.~~	The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R5.	N/A	N/A	N/A	The responsible entity does not have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, or the transient voltage response for its System.
R6.	N/A	N/A	N/A	The responsible entity failed to define and document the criteria or methodology for System instability used within its analysis as described in Requirement R6.
R7.	N/A	N/A	N/A	The Planning Coordinator, in conjunction with each of its Transmission Planners, failed to determine and identify individual or joint responsibilities for performing required studies.

0	February 8, 2005	BOT Approval	Revised
0	June 3, 2005	Fixed reference in M1 to read TPL-001-0 R2.1 and TPL-001-0 R2.2	Errata
0	July 24, 2007	Corrected reference in M1. to read TPL-001-0 R1 and TPL-001-0 R2.	Errata
0.1	October 29, 2008	BOT adopted errata changes; updated version number to "0.1"	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote 'b' pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC	

Version	Date	Action	Change Tracking
		has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-3 was created after the Board of Trustees approved the revised footnote 'b' in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	TBD	Adopted by the NERC Board of Trustees.	Revised To address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

~~I. Stakeholder Process~~

~~During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. .The process must include the following:~~

1. ~~Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues~~
2. ~~Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:~~
   a. ~~Date, time, and location for the meeting~~
   b. ~~Specific location(s) of the planned Non-Consequential Load Loss under footnote 12~~
   c. ~~Provisions for a stakeholder comment period~~
3. ~~Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants~~
4. ~~A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns~~
5. ~~A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction~~

~~An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.~~

~~II. Information for Inclusion in Item #3 of the Stakeholder Process~~

~~The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:~~

1. ~~Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:~~
   a. ~~System Load level and estimated annual hours of exposure at or above that Load level~~
   b. ~~Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency~~
2. ~~Amount of Non-Consequential Load Loss with:~~
   a. ~~The estimated number and type of customers affected~~

b. ~~An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community~~

3. ~~Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance~~

4. ~~Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance~~

5. ~~Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12~~

6. ~~Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12~~

7. ~~Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12~~

8. ~~Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators~~

~~III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required~~

~~Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:~~

1. ~~The voltage level of the Contingency is greater than 300 kV~~

   a. ~~If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or~~

   b. ~~For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)~~

~~The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW~~

~~Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.~~

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability: a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. d. Simulate Normal Clearing unless otherwise specified. e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only**: f. Applicable Facility Ratings shall not be exceeded. g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. h. Planning event P0 is applicable to steady state only. i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only:** j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event[1]	Fault Type[2]	BES Level[3]	Interruption of Firm Transmission Service Allowed[4]	Non-Consequential Load Loss Allowed
P0 No Contingency	Normal System	None	N/A	EHV, HV	No	No
P1 Single Contingency	Normal System	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer[5] 4. Shunt Device[6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single Pole of a DC line	SLG			
P2 Single Contingency	Normal System	1. Opening of a line section w/o a fault[7]	N/A	EHV, HV	No[9]	No[12]
		2. Bus Section Fault	SLG	EHV	No[9]	No
				HV	Yes	Yes
		3. Internal Breaker Fault[8] (non-Bus-tie Breaker)	SLG	EHV	No[9]	No
				HV	Yes	Yes
		4. Internal Breaker Fault (Bus-tie Breaker)[8]	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P3 Multiple Contingency	Loss of generator unit followed by System adjustments[9]	Loss of one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6]	3Ø	EHV, HV	No[9]	No[12]
		5. Single pole of a DC line	SLG			
P4 Multiple Contingency *(Fault plus stuck breaker[10])*	Normal System	Loss of multiple elements caused by a stuck breaker [10](non-Bus-tie Breaker) attempting to clear a Fault on one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
		6. Loss of multiple elements caused by a stuck breaker[10] (Bus-tie Breaker) attempting to clear a Fault on the associated bus	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P5 Multiple Contingency *(Fault plus ~~relay~~ non-redundant component of a Protection System failure to operate)*	Normal System	Delayed Fault Clearing due to the failure of a non-redundant ~~relay~~ component of a Protection System[13] protecting the Faulted element to operate as designed, for one of the following: 1. Generator 2. Transmission Circuit 3. Transformer [5] 4. Shunt Device [6] 5. Bus Section	SLG	EHV	No[9]	No
				HV	Yes	Yes
P6 Multiple Contingency *(Two overlapping singles)*	Loss of one of the following followed by System adjustments.[9] 1. Transmission Circuit 2. Transformer [5] 3. Shunt Device[6] 4. Single pole of a DC line	Loss of one of the following: 1. Transmission Circuit 2. Transformer [5] 3. Shunt Device [6]	3Ø	EHV, HV	Yes	Yes
		4. Single pole of a DC line	SLG	EHV, HV	Yes	Yes

Category	Initial Condition	Event [1]	Fault Type [2]	BES Level [3]	Interruption of Firm Transmission Service Allowed [4]	Non-Consequential Load Loss Allowed
P7 Multiple Contingency *(Common Structure)*	Normal System	The loss of: 1. Any two adjacent (vertically or horizontally) circuits on common structure [11] 2. Loss of a bipolar DC line	SLG	EHV, HV	Yes	Yes

Table 1 – Steady State & Stability Performance Extreme Events

Steady State & Stability

For all extreme events evaluated:

a. Simulate the removal of all elements that Protection Systems and automatic controls are expected to disconnect for each Contingency.
b. Simulate Normal Clearing unless otherwise specified.

Steady State

1. Loss of a single generator, Transmission Circuit, single pole of a DC Line, shunt device, or transformer forced out of service followed by another single generator, Transmission Circuit, single pole of a different DC Line, shunt device, or transformer forced out of service prior to System adjustments.
2. Local area events affecting the Transmission System such as:
   a. Loss of a tower line with three or more circuits.[11]
   b. Loss of all Transmission lines on a common Right-of-Way[11].
   c. Loss of a switching station or substation (loss of one voltage level plus transformers).
   d. Loss of all generating units at a generating station.
   e. Loss of a large Load or major Load center.
3. Wide area events affecting the Transmission System based on System topology such as:
   a. Loss of two generating stations resulting from conditions such as:
      i. Loss of a large gas pipeline into a region or multiple regions that have significant gas-fired generation.
      ii. Loss of the use of a large body of water as the cooling source for generation.

Stability

1. With an initial condition of a single generator, Transmission circuit, single pole of a DC line, shunt device, or transformer forced out of service, apply a 3Ø fault on another single generator, Transmission circuit, single pole of a different DC line, shunt device, or transformer prior to System adjustments.
2. Local or wide area events affecting the Transmission System such as:
   a. 3Ø fault on generator with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
   b. 3Ø fault on Transmission circuit with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
   c. 3Ø fault on transformer with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
   d. 3Ø fault on bus section with stuck breaker[10] ~~or a relay failure[13]~~ resulting in Delayed Fault Clearing.
   e. 3Ø fault on generator with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.
   f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing.

iii. Wildfires. iv. Severe weather, e.g., hurricanes, tornadoes, etc. v. A successful cyber attack. vi. Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. ~~d.~~i. 3Ø internal breaker fault. ~~e.~~j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss.
2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria.
3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss.
4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service.
5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers.
6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground.
7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point.
8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker.
9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered.

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing.
11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less.
12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction.
13. For purposes of this standard, non-redundant components of a Protection System to consider are as follows: 1. A single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying; 2. A single communications system, necessary for correct operation of a communication-aid protection scheme required for Normal Clearing, which is not monitored or not reported; 3. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit; 4. A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.~~Applies to the following relay functions or types: pilot (#85), distance (#21), differential (#87), current (#50, 51, and 67), voltage (#27 & 59), directional (#32, & 67), and tripping (#86, & 94).~~

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. The process must include the following:

~~6.~~1. Meetings must be open to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues
~~7.~~2. Notice must be provided in advance of meetings to affected stakeholders including applicable regulatory authorities or governing bodies responsible for retail electric service issues and include an agenda with:
    a. Date, time, and location for the meeting
    b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
    c. Provisions for a stakeholder comment period
~~8.~~3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
~~9.~~4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
~~10.~~5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

~~9.~~1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
    a. System Load level and estimated annual hours of exposure at or above that Load level
    b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency
~~10.~~2. Amount of Non-Consequential Load Loss with:
    a. The estimated number and type of customers affected

b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community

~~11.~~3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance

~~12.~~4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance

~~13.~~5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12

~~14.~~6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12

~~15.~~7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12

~~16.~~8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

~~2.~~1. The voltage level of the Contingency is greater than 300 kV

a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or

b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)

~~3.~~2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the first draft of the proposed standard.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	October 29, 2015
SAR posted for comment	May 26 – June 24, 2016
30-day Informal Comment Period	April 25 – May 24, 2017

Anticipated Actions	Date
45-day formal comment period with initial ballot	September 2017
45-day formal comment period with additional ballot	November 2017
10-day final ballot	February 2018
Board adoption	May 2018

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None.

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**
2. **Number:** **TPL-001-5**
3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.
4. **Applicability:**
   4.1. Functional Entity
   4.1.1. Planning Coordinator.
   4.1.2. Transmission Planner.
5. **Effective Date: See Implementation Plan.**

B. Requirements and Measures

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities.

1.1.2. Known outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

1.1.3. New planned Facilities and changes to existing Facilities.

1.1.4. Real and reactive Load forecasts.

1.1.5. Known commitments for Firm Transmission Service and Interchange.

1.1.6. Resources (supply or demand side) required for Load .

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with MOD-032 including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. P1 events in Table 1, ~~as selected in consultation with the Reliability Coordinator,~~ with known outages modeled as ~~specified~~ in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.1.4. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response:

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be ~~studied~~ assessed. The

~~studies~~analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. P1 events in Table 1, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.4.4. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.

- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be ~~studied. The studies~~assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 ~~categories~~category events identified in Table 1 ~~with~~for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or ~~Special Protection Systems~~ Remedial Action Scheme.
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5.

3.3. Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES shall be identified, and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies, of the studies utilized in preparing the Planning Assessment, in accordance with Requirement R3.

R4. For the Stability portion of the Planning Assessment, as described in Requirement R2, Parts 2.4 and 2.5, each Transmission Planner and Planning Coordinator shall perform the Contingency analyses listed in Table 1. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

4.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R4, Part 4.4.

4.1.1. For planning event P1: No generating unit shall pull out of synchronism. A generator being disconnected from the System by fault clearing action or by a ~~Special Protection System~~Remedial Action Scheme is not considered pulling out of synchronism.

4.1.2. For planning events P2 through P7: When a generator pulls out of synchronism in the simulations, the resulting apparent impedance swings shall not result in the tripping of any Transmission system elements other than the generating unit and its directly connected Facilities.

4.1.3. For planning events P1 through P7: Power oscillations shall exhibit acceptable damping as established by the Planning Coordinator and Transmission Planner.

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.2.1. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation.

~~4.1.3.1.~~4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

~~4.2.~~4.3. Contingency analyses for Requirement R4, Parts 4.1 and 4.2 shall:

~~4.2.1.~~4.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

~~4.2.1.1.~~4.3.1.1. Successful high speed (less than one second) reclosing and unsuccessful high speed reclosing into a Fault where high speed reclosing is utilized.

~~4.2.1.2.~~4.3.1.2. Tripping of generators where simulations show generator bus voltages or high side of the GSU voltages are less than known or assumed generator low voltage ride through capability. Include in the assessment any assumptions made.

~~4.2.1.3.~~4.3.1.3. Tripping of Transmission lines and transformers where transient swings cause Protection System operation based on generic or actual relay models.

~~4.2.2.~~4.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide dynamic control of electrical system quantities when such devices impact the study area. These devices may include equipment such as generation exciter control and power system stabilizers, static var compensators, power flow controllers, and DC Transmission controllers.

~~4.3.~~4.4. Those planning events in Table 1 that are expected to produce more severe System impacts on its portion of the BES, shall be identified, and a list created of those Contingencies to be evaluated in Requirement R4, Part 4.1.

The rationale for those Contingencies selected for evaluation shall be available as supporting information.

~~4.3.1.~~4.4.1. Each Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

~~4.4.~~4.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R4, Part 4.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. ~~If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.~~

~~4.5.~~ ~~If the analysis concludes there is Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h, a Corrective Action Plan shall be developed. The Corrective Action Plan shall:~~

~~4.5.1.~~ ~~List System deficiencies and the associated actions needed to prevent the System from Cascading.~~

~~4.5.2.~~ ~~Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.~~

M4. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R4.

R5. Each Transmission Planner and Planning Coordinator shall have criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System. For transient voltage response, the criteria shall at a minimum, specify a low voltage level and a maximum length of time that transient voltages may remain below that level. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M5. Each Transmission Planner and Planning Coordinator shall provide dated evidence such as electronic or hard copies of the documentation specifying the criteria for acceptable System steady state voltage limits, post-Contingency voltage deviations, and the transient voltage response for its System in accordance with Requirement R5.

R6. Each Transmission Planner and Planning Coordinator shall define and document, within their Planning Assessment, the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

M6. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of documentation specifying the criteria or methodology used in the analysis to identify System instability for conditions such as Cascading, voltage instability, or uncontrolled islanding that was utilized in preparing the Planning Assessment in accordance with Requirement R6.

R7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall determine and identify each entity's individual and joint responsibilities for performing the required studies for the Planning Assessment. *[Violation Risk Factor: Low] [Time Horizon: Long-term Planning]*

M7. Each Planning Coordinator, in conjunction with each of its Transmission Planners, shall provide dated documentation on roles and responsibilities, such as meeting minutes, agreements, and e-mail correspondence that identifies that agreement has been reached on individual and joint responsibilities for performing the required studies and Assessments in accordance with Requirement R7.

R8. Each Planning Coordinator and Transmission Planner shall distribute its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 calendar days of completing its Planning Assessment, and to any functional entity that has a reliability related need and submits a written request for the information within 30 days of such a request. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

8.1. If a recipient of the Planning Assessment results provides documented comments on the results, the respective Planning Coordinator or Transmission Planner shall provide a documented response to that recipient within 90 calendar days of receipt of those comments.

M8. Each Planning Coordinator and Transmission Planner shall provide evidence, such as email notices, documentation of updated web pages, postal receipts showing recipient and date; or a demonstration of a public posting, that it has distributed its Planning Assessment results to adjacent Planning Coordinators and adjacent Transmission Planners within 90 days of having completed its Planning Assessment, and to any functional entity who has indicated a reliability need within 30 days of a written request and that the Planning Coordinator or Transmission Planner has provided a documented response to comments received on Planning Assessment results within 90 calendar days of receipt of those comments in accordance with Requirement R8.

C. Compliance

1. Compliance Monitoring Process

1.1. Compliance Enforcement Authority: "Compliance Enforcement Authority" means NERC or the Regional Entity, or any entity as otherwise designated by an Applicable Governmental Authority, in their respective roles of monitoring and/or enforcing compliance with mandatory and enforceable Reliability Standards in their respective jurisdictions.

1.2. Evidence Retention: The following evidence retention period(s) identify the period of time an entity is required to retain specific evidence to demonstrate compliance. For instances where the evidence retention period specified below is shorter than the time since the last audit, the Compliance Enforcement Authority may ask an entity to provide other evidence to show that it was compliant for the full-time period since the last audit

The applicable entity shall keep data identified in Measures M1 through ~~M7~~M8 or evidence to show compliance as identified below unless directed by its Compliance Enforcement Authority to retain specific evidence for a longer period of time as part of an investigation.

- Each Responsible Entity shall retain evidence of each requirement in this standard for three calendar years.

1.3. Compliance Monitoring and Enforcement Program As defined in the NERC Rules of Procedure, "Compliance Monitoring and Enforcement Program" refers to the identification of the processes that will be used to evaluate data or information for the purpose of assessing performance or outcomes with the associated Reliability Standard.

1.4. Compliance Monitoring Period and Reset Timeframe: Not applicable.

1.5. Compliance Monitoring and Enforcement Processes:

- Compliance Audits
- Self-Certifications
- Spot Checks
- Compliance Investigations
- Self-Reports
- Complaints

1.6. Additional Compliance Information: None.

Violation Severity Levels

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R1.	The responsible entity's System model failed to represent one of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent two of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent three of the Requirement R1, Parts 1.1.1 through 1.1.6.	The responsible entity's System model failed to represent four or more of the Requirement R1, Parts 1.1.1 through 1.1.6. OR The responsible entity's System model did not represent projected System conditions as described in Requirement R1. OR The responsible entity's System model did not use data consistent with that provided in accordance with the MOD-032 standards and other sources, including items represented in the Corrective Action Plan.
R2.	The responsible entity failed to comply with Requirement R2, Part 2.6.	The responsible entity failed to comply with Requirement R2, Part 2.3 or Part 2.8.	The responsible entity failed to comply with one of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, Part 2.5, or Part 2.7.	The responsible entity failed to comply with two or more of the following Parts of Requirement R2: Part 2.1, Part 2.2, Part 2.4, or Part 2.7. OR The responsible entity does not have a completed annual Planning Assessment.

R #	Violation Severity Levels			
	Lower VSL	Moderate VSL	High VSL	Severe VSL
R3.	The responsible entity did not identify planning events as described in Requirement R3, Part 3.4 or extreme events as described in Requirement R3, Part 3.5.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for one of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies as specified in Requirement R3, Part 3.2 to assess the impact of extreme events.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for two of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform Contingency analysis as described in Requirement R3, Part 3.3.	The responsible entity did not perform studies as specified in Requirement R3, Part 3.1 to determine that the BES meets the performance requirements for three or more of the categories (P2 through P7) in Table 1. OR The responsible entity did not perform studies to determine that the BES meets the performance requirements for the P0 or P1 categories in Table 1. OR The responsible entity did not base its studies on computer simulation models using data provided in Requirement R1.
R4.	The responsible entity did not identify planning events as described in Requirement R4, Part 4.4 or extreme events as described in Requirement R4, Part 4.5.	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements	The responsible entity did not perform studies as specified in Requirement R4, Part 4.1 to determine that the BES meets the performance requirements for three or more of the categories (P1 through P7) in Table 1.

Version History

Version	Date	Action	Change Tracking
0	April 1, 2005	Effective Date	New
0	February 8, 2005	BOT Approval	Revised
0	June 3, 2005	Fixed reference in M1 to read TPL-001-0 R2.1 and TPL-001-0 R2.2	Errata
0	July 24, 2007	Corrected reference in M1. to read TPL-001-0 R1 and TPL-001-0 R2.	Errata
0.1	October 29, 2008	BOT adopted errata changes; updated version number to “0.1”	Errata
0.1	May 13, 2009	FERC Approved – Updated Effective Date and Footer	Revised
1	Approved by Board of Trustees February 17, 2011	Revised footnote ‘b’ pursuant to FERC Order RM06-16-009	Revised (Project 2010-11)
2	August 4, 2011	Revision of TPL-001-1; includes merging and upgrading requirements of TPL-001-0, TPL-002-0, TPL-003-0, and TPL-004-0 into one, single, comprehensive, coordinated standard: TPL-001-2; and retirement of TPL-005-0 and TPL-006-0.	Project 2006-02 – complete revision
2	August 4, 2011	Adopted by Board of Trustees	
1	April 19, 2012	FERC issued Order 762 remanding TPL-001-1, TPL-002-1b, TPL-003-1a, and TPL-004-1. FERC also issued a NOPR proposing to remand TPL-001-2. NERC	

Version	Date	Action	Change Tracking
		has been directed to revise footnote 'b' in accordance with the directives of Order Nos. 762 and 693.	
3	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-3 was created after the Board of Trustees approved the revised footnote 'b' in TPL-002-2b, which was balloted and appended to: TPL-001-0.1, TPL-002-0b, TPL-003-0a, and TPL-004-0.	
4	February 7, 2013	Adopted by the NERC Board of Trustees. TPL-001-4 was adopted by the Board of Trustees as TPL-001-3, but a discrepancy in numbering was identified and corrected prior to filing with the regulatory agencies.	
4	October 17, 2013	FERC Order issued approving TPL-001-4 (Order effective December 23, 2013).	
4	May 7, 2014	NERC Board of Trustees adopted change to VRF in Requirement 1 from Medium to High.	Revision
4	November 26, 2014	FERC issued a letter order approving change to VRF in Requirement 1 from Medium to High.	
5	TBD	Adopted by the NERC Board of Trustees.	Revised To address reliability issues as identified in FERC Order No. 754 and Order No. 786 directives and update the references to the MOD Reliability Standards in TPL-001.

Table 1 – Steady State & Stability Performance Planning Events
Steady State & Stability: a. The System shall remain stable. Cascading and uncontrolled islanding shall not occur. b. Consequential Load Loss as well as generation loss is acceptable as a consequence of any event excluding P0. c. Simulate the removal of all elements that Protection Systems and other controls are expected to automatically disconnect for each event. d. Simulate Normal Clearing unless otherwise specified. e. Planned System adjustments such as Transmission configuration changes and re-dispatch of generation are allowed if such adjustments are executable within the time duration applicable to the Facility Ratings. **Steady State Only**: f. Applicable Facility Ratings shall not be exceeded. g. System steady state voltages and post-Contingency voltage deviations shall be within acceptable limits as established by the Planning Coordinator and the Transmission Planner. h. Planning event P0 is applicable to steady state only. i. The response of voltage sensitive Load that is disconnected from the System by end-user equipment associated with an event shall not be used to meet steady state performance requirements. **Stability Only:** j. Transient voltage response shall be within acceptable limits established by the Planning Coordinator and the Transmission Planner.

Category	Initial Condition	Event [1]	Fault Type[2]	BES Level[3]	Interruption of Firm Transmission Service Allowed[4]	Non-Consequential Load Loss Allowed

Table 1 – Steady State & Stability Performance Extreme Events	
ii. Loss of the use of a large body of water as the cooling source for generation. iii. Wildfires. iv. Severe weather, e.g., hurricanes, tornadoes, etc. v. A successful cyber attack. vi. Shutdown of a nuclear power plant(s) and related facilities for a day or more for common causes such as problems with similarly designed plants. b. Other events based upon operating experience that may result in wide area disturbances.	f. 3Ø fault on Transmission circuit with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. g. 3Ø fault on transformer with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. h. 3Ø fault on bus section with failure of a non-redundant component of a Protection System[13] resulting in Delayed Fault Clearing. i. 3Ø internal breaker fault. j. Other events based upon operating experience, such as consideration of initiating events that experience suggests may result in wide area disturbances

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
1. If the event analyzed involves BES elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed event determines the stated performance criteria regarding allowances for interruptions of Firm Transmission Service and Non-Consequential Load Loss. 2. Unless specified otherwise, simulate Normal Clearing of faults. Single line to ground (SLG) or three-phase (3Ø) are the fault types that must be evaluated in Stability simulations for the event described. A 3Ø or a double line to ground fault study indicating the criteria are being met is sufficient evidence that a SLG condition would also meet the criteria. 3. Bulk Electric System (BES) level references include extra-high voltage (EHV) Facilities defined as greater than 300kV and high voltage (HV) Facilities defined as the 300kV and lower voltage Systems. The designation of EHV and HV is used to distinguish between stated performance criteria allowances for interruption of Firm Transmission Service and Non-Consequential Load Loss. 4. Curtailment of Conditional Firm Transmission Service is allowed when the conditions and/or events being studied formed the basis for the Conditional Firm Transmission Service. 5. For non-generator step up transformer outage events, the reference voltage, as used in footnote 1, applies to the low-side winding (excluding tertiary windings). For generator and Generator Step Up transformer outage events, the reference voltage applies to the BES connected voltage (high-side of the Generator Step Up transformer). Requirements which are applicable to transformers also apply to variable frequency transformers and phase shifting transformers. 6. Requirements which are applicable to shunt devices also apply to FACTS devices that are connected to ground. 7. Opening one end of a line section without a fault on a normally networked Transmission circuit such that the line is possibly serving Load radial from a single source point. 8. An internal breaker fault means a breaker failing internally, thus creating a System fault which must be cleared by protection on both sides of the breaker. 9. An objective of the planning process should be to minimize the likelihood and magnitude of interruption of Firm Transmission Service following Contingency events. Curtailment of Firm Transmission Service is allowed both as a System adjustment (as identified in the column entitled 'Initial Condition') and a corrective action when achieved through the appropriate re-dispatch of resources obligated to re-dispatch, where it can be demonstrated that Facilities, internal and external to the Transmission Planner's planning region, remain within

Table 1 – Steady State & Stability Performance Footnotes (Planning Events and Extreme Events)
applicable Facility Ratings and the re-dispatch does not result in any Non-Consequential Load Loss. Where limited options for re-dispatch exist, sensitivities associated with the availability of those resources should be considered. 10. A stuck breaker means that for a gang-operated breaker, all three phases of the breaker have remained closed. For an independent pole operated (IPO) or an independent pole tripping (IPT) breaker, only one pole is assumed to remain closed. A stuck breaker results in Delayed Fault Clearing. 11. Excludes circuits that share a common structure (Planning event P7, Extreme event steady state 2a) or common Right-of-Way (Extreme event, steady state 2b) for 1 mile or less. 12. An objective of the planning process is to minimize the likelihood and magnitude of Non-Consequential Load Loss following planning events. In limited circumstances, Non-Consequential Load Loss may be needed throughout the planning horizon to ensure that BES performance requirements are met. However, when Non-Consequential Load Loss is utilized under footnote 12 within the Near-Term Transmission Planning Horizon to address BES performance requirements, such interruption is limited to circumstances where the Non-Consequential Load Loss meets the conditions shown in Attachment 1. In no case can the planned Non-Consequential Load Loss under footnote 12 exceed 75 MW for US registered entities. The amount of planned Non-Consequential Load Loss for a non-US Registered Entity should be implemented in a manner that is consistent with, or under the direction of, the applicable governmental authority or its agency in the non-US jurisdiction. 13. For purposes of this standard, non-redundant components of a Protection System to consider are~~ as follows~~: a. A single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying; b. A single communications system, necessary for correct operation of ~~protective functions~~ a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported; c. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit; d. A single control circuitry associated with protective functions ~~through~~including the trip coil(s) of the circuit breakers or other interrupting devices.

Attachment 1

I. Stakeholder Process

During each Planning Assessment before the use of Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in the Near-Term Transmission Planning Horizon of the Planning Assessment, the Transmission Planner or Planning Coordinator shall ensure that the utilization of footnote 12 is reviewed through an open and transparent stakeholder process. The responsible entity can utilize an existing process or develop a new process. The process must include the following:

1. Meetings must be open to affected stakeholders, including applicable regulatory authorities or governing bodies responsible for retail electric service issues
2. Notice must be provided in advance of meetings to affected stakeholders, including applicable regulatory authorities or governing bodies responsible for retail electric service issues, and include an agenda with:
   a. Date, time, and location for the meeting
   b. Specific location(s) of the planned Non-Consequential Load Loss under footnote 12
   c. Provisions for a stakeholder comment period
3. Information regarding the intended purpose and scope of the proposed Non-Consequential Load Loss under footnote 12 (as shown in Section II below) must be made available to meeting participants
4. A procedure for stakeholders to submit written questions or concerns and to receive written responses to the submitted questions and concerns
5. A dispute resolution process for any question or concern raised in #4 above that is not resolved to the stakeholder's satisfaction

An entity does not have to repeat the stakeholder process for a specific application of footnote 12 utilization with respect to subsequent Planning Assessments unless conditions spelled out in Section II below have materially changed for that specific application.

II. Information for Inclusion in Item #3 of the Stakeholder Process

The responsible entity shall document the planned use of Non-Consequential Load Loss under footnote 12 which must include the following:

1. Conditions under which Non-Consequential Load Loss under footnote 12 would be necessary:
   a. System Load level and estimated annual hours of exposure at or above that Load level
   b. Applicable Contingencies and the Facilities outside their applicable rating due to that Contingency
2. Amount of Non-Consequential Load Loss with:
   a. The estimated number and type of customers affected

   b. An explanation of the effect of the use of Non-Consequential Load Loss under footnote 12 on the health, safety, and welfare of the community

3. Estimated frequency of Non-Consequential Load Loss under footnote 12 based on historical performance
4. Expected duration of Non-Consequential Load Loss under footnote 12 based on historical performance
5. Future plans to alleviate the need for Non-Consequential Load Loss under footnote 12
6. Verification that TPL Reliability Standards performance requirements will be met following the application of footnote 12
7. Alternatives to Non-Consequential Load Loss considered and the rationale for not selecting those alternatives under footnote 12
8. Assessment of potential overlapping uses of footnote 12 including overlaps with adjacent Transmission Planners and Planning Coordinators

III. Instances for which Regulatory Review of Non-Consequential Load Loss under Footnote 12 is Required

Before a Non-Consequential Load Loss under footnote 12 is allowed as an element of a Corrective Action Plan in Year One of the Planning Assessment, the Transmission Planner or Planning Coordinator must ensure that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12 if either:

1. The voltage level of the Contingency is greater than 300 kV
   a. If the Contingency analyzed involves BES Elements at multiple System voltage levels, the lowest System voltage level of the element(s) removed for the analyzed Contingency determines the stated performance criteria regarding allowances for Non-Consequential Load Loss under footnote 12, or
   b. For a non-generator step up transformer outage Contingency, the 300 kV limit applies to the low-side winding (excluding tertiary windings). For a generator or generator step up transformer outage Contingency, the 300 kV limit applies to the BES connected voltage (high-side of the Generator Step Up transformer)
2. The planned Non-Consequential Load Loss under footnote 12 is greater than or equal to 25 MW.

Once assurance has been received that the applicable regulatory authorities or governing bodies responsible for retail electric service issues do not object to the use of Non-Consequential Load Loss under footnote 12, the Planning Coordinator or Transmission Planner must submit the information outlined in items II.1 through II.8 above to the ERO for a determination of whether there are any Adverse Reliability Impacts caused by the request to utilize footnote 12 for Non-Consequential Load Loss.

Implementation Plan

Project 2015-10 Single Points of Failure Reliability Standard TPL-001-5

Applicable Standard(s)

- TPL-001-5 – Transmission System Planning Performance Requirements

Requested Retirement(s)

- TPL-001-4 – Transmission System Planning Performance Requirements

Prerequisite Standard(s)

- None

Applicable Entities

- Planning Coordinator
- Transmission Planner

Background

Reliability Standard TPL-001-5 revises the prior version of the TPL-001 standard in three key respects:

- To address reliability issues concerning the study of single points of failure on Protection Systems, as identified in Federal Energy Regulatory Commission (FERC) Order No. 754 issued September 15, 2011, and the NERC Planning Committee System Protection and Control Subcommittee and System Analysis and Modeling Subcommittee September 2015 report titled *Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request;*
- To address directives from FERC Order No. 786 issued October 17, 2013, in which FERC approved Reliability Standard TPL-001-4; and
- To replace references to the MOD-010 and MOD-012 standards, which have been superseded by the MOD-032 Reliability Standard.

General Considerations

The 36-month implementation period for TPL-001-5 provides Planning Coordinators and Transmission Planners with time to update their annual Planning Assessments to include the new System models and studies required by the standard. This implementation period reflects consideration that Planning Coordinators and Transmission Planners will need time to develop, among other things:

- A process for coordinating with the Reliability Coordinator which known outages of generation of Transmission Facilities of less than six months shall be represented in planning studies;
- A process for establishing coordination with protection engineers to obtain the necessary data to perform the single points of failure analysis required by the standard; and
- Additional base case models and analysis.

In addition, the implementation plan includes an additional 24 month period for the development of Corrective Action Plans under TPL-001-5 to address newly-added studies involving single points of failure on Protection Systems. This implementation period reflects consideration that Planning Coordinators and Transmission Planners will need time beyond that provided to conduct the new studies and analysis to develop processes for coordination with asset owners and protection engineers to identify appropriate Corrective Action Plan actions and establish the associated timetables for completion. This includes any necessary Corrective Action Plans to address System performance issues for studies involving Table 1 Category P5 Multiple Contingency (Fault plus non-redundant component of a Protection System failure to operate) required by TPL-001-5 Requirement R2 Part 2.7 for the following non-redundant components of a Protection System identified in TPL-001-5 Table 1 Footnote 13, items 2-4:

- A single communications system, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported;
- A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit;
- A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.

Lastly, the provisions related to Corrective Action Plans including Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3) are carried forward from the TPL-001-4 implementation plan.

Effective Date

TPL-001-5 – Transmission System Planning Performance Requirements

Where approval by an applicable governmental authority is required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Compliance Date for TPL-001-5 Requirement 2, Part 2.7 associated with Table 1 Category P5 Footnote 13 items 2, 3, and 4

Entitles shall not be required to comply with Requirement R2, Part 2.7 for the Table 1 Category P5 planning event for the non-redundant components of a Protection System identified in footnote 13 items 2, 3, and 4 until 24 months after the effective date of Reliability Standard TPL-001-5.

Note Regarding Corrective Action Plans

For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval of TPL-001-4, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-5, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-5:

- P1-2 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)
- P1-3 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)
- P2-1
- P2-2 (above 300 kV)
- P2-3 (above 300 kV)
- P3-1 through P3-5
- P4-1 through P4-5 (above 300 kV)
- P5 (above 300 kV)

Initial Performance of Periodic Requirements

Each responsible entity shall complete the first annual Planning Assessment in accordance with TPL-001-5 by the effective date of the standard.

Each responsible entity shall complete any required Corrective Action Plans under Requirement R2, Part 2.7 associated with the non-redundant components of a Protection System identified in Table 1 Category P5 Footnote 13 items 2, 3, and 4 by 24 months after the effective date of Reliability Standard TPL-001-5.

Retirement Date

TPL-001-4 – Transmission System Planning Performance Requirements

Reliability Standard TPL-001-4 shall be retired immediately prior to the effective date of TPL-001-5 in the particular jurisdiction in which the revised standard is becoming effective.

Implementation Plan

Project 2015-10 Single Points of Failure
Reliability Standard TPL-001-5

Applicable Standard(s)

- TPL-001-5 – Transmission System Planning Performance Requirements

Requested Retirement(s)

- TPL-001-4 – Transmission System Planning Performance Requirements

Prerequisite Standard(s)

- None

Applicable Entities

- Planning Coordinator
- Transmission Planner

Background

Reliability Standard TPL-001-5 revises the prior version of the TPL-001 standard in three key respects:

- To address reliability issues concerning the study of single points of failure on Protection Systems, as identified in Federal Energy Regulatory Commission (FERC) Order No. 754 issued September 15, 2011, and the NERC Planning Committee System Protection and Control Subcommittee and System Analysis and Modeling Subcommittee September 2015 report titled *Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request;*
- To address directives from FERC Order No. 786 issued October 17, 2013, in which FERC approved Reliability Standard TPL-001-4; and
- To replace references to the MOD-010 and MOD-012 standards, which have been superseded by the MOD-032 Reliability Standard.

General Considerations

The 36-month implementation period for TPL-001-5 provides Planning Coordinators and Transmission Planners with time to update their annual Planning Assessments to include the new System models and studies required by the standard. This implementation period reflects consideration that Planning Coordinators and Transmission Planners will need time to develop, among other things:

- A process for coordinating with the Reliability Coordinator which known outages of generation of Transmission Facilities of less than six months shall be represented in planning studies;
- A process for establishing coordination with protection engineers to obtain the necessary data to perform the single points of failure analysis required by the standard; and
- Additional base case models and analysis.

In addition, the implementation plan includes an additional 24 month period for the development of Corrective Action Plans under TPL-001-5 to address newly-added studies involving single points of failure on Protection Systems. This implementation period reflects consideration that Planning Coordinators and Transmission Planners will need time beyond that provided to conduct the new studies and analysis to develop processes for coordination with asset owners and protection engineers to identify appropriate Corrective Action Plan actions and establish the associated timetables for completion. This includes~~:~~

- ~~Any necessary Corrective Action Plans to address Cascading caused by the occurrence of Table 1 extreme events listed in the stability column for events 2e-2h required by TPL-001-5 Requirement R4 Part 4.6; and~~

~~Any~~ any necessary Corrective Action Plans to address System performance issues for studies involving Table 1 Category P5 Multiple Contingency (Fault plus non-redundant component of a Protection System failure to operate) required by TPL-001-5 Requirement R2 Part 2.7 for the following non-redundant components of a Protection System identified in TPL-001-5 Table 1 Footnote 13, items 2-4:

- A single communications system, necessary for correct operation of ~~protective functions~~ a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported;
- A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit;
- A single control circuitry associated with protective functions ~~through~~including the trip coil(s) of the circuit breakers or other interrupting devices.

Lastly, the provisions related to Corrective Action Plans including Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3) are carried forward from the TPL-001-4 implementation plan.

Effective Date

TPL-001-5 – Transmission System Planning Performance Requirements

Where approval by an applicable governmental authority is required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the effective date of the applicable governmental authority's order approving the standard, or as otherwise provided by the applicable governmental authority.

Where approval by an applicable governmental authority is not required, the standard shall become effective on the first day of the first calendar quarter that is 36 months after the date the standard is adopted by the NERC Board of Trustees, or as otherwise provided for in that jurisdiction.

Compliance Date for TPL-001-5 Requirement ~~R4, Part 4.6 and Requirement~~ 2, Part 2.7 associated with Table 1 Category P5 Footnote 13 items 2, 3, and 4

~~Entities shall not be required to comply with Requirement R4, Part 4.6 until 24 months after the effective date of Reliability Standard TPL-001-5.~~

Entitles shall not be required to comply with Requirement R2, Part 2.7 for the Table 1 Category P5 planning event for the non-redundant components of a Protection System identified in footnote 13 items 2, 3, and 4 until 24 months after the effective date of Reliability Standard TPL-001-5.

Note Regarding Corrective Action Plans

For 84 calendar months beginning the first day of the first calendar quarter following applicable regulatory approval of TPL-001-4, or in those jurisdictions where regulatory approval is not required on the first day of the first calendar quarter 84 months after Board of Trustees adoption or as otherwise made effective pursuant to the laws applicable to such ERO governmental authorities, Corrective Action Plans applying to the following categories of Contingencies and events identified in TPL-001-5, Table 1 are allowed to include Non-Consequential Load Loss and curtailment of Firm Transmission Service (in accordance with Requirement R2, Part 2.7.3.) that would not otherwise be permitted by the requirements of TPL-001-5:

- P1-2 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)
- P1-3 (for controlled interruption of electric supply to local network customers connected to or supplied by the Faulted element)
- P2-1
- P2-2 (above 300 kV)
- P2-3 (above 300 kV)
- P3-1 through P3-5
- P4-1 through P4-5 (above 300 kV)
- P5 (above 300 kV)

Initial Performance of Periodic Requirements

Each responsible entity shall complete the first annual Planning Assessment in accordance with TPL-001-5 by the effective date of the standard.

Each responsible entity shall complete any required Corrective Action Plans under Requirement ~~R4, Part 4.6 and Requirement~~ R2, Part 2.7 associated with the non-redundant components of a

Protection System identified in Table 1 Category P5 Footnote 13 items 2, 3, and 4 by 24 months after the effective date of Reliability Standard TPL-001-5.

Retirement Date

TPL-001-4 – Transmission System Planning Performance Requirements

Reliability Standard TPL-001-4 shall be retired immediately prior to the effective date of TPL-001-5 in the particular jurisdiction in which the revised standard is becoming effective.

Unofficial Comment Form

Project 2015-10 Single Points of Failure TPL-001

Do not use this form for submitting comments. Use the electronic form to submit comments on **TPL-001-5 – Transmission System Planning Performance Requirements**. The electronic form must be submitted by **8 p.m. Eastern, Monday, October 23, 2017.**

Additional information is available on the project page. If you have questions, contact Standards Developer, Latrice Harkness (via email), or at 404-446-9728.

Background Information

The SPCS and the SAMS conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action**.**

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Questions

1. Do you agree that an associated timetable for implementation of actions needed to prevent the System from Cascading (TPL-001-5 Requirement R4, Part 4.2.2.1) and an annual review of implementation status (TPL-001-5 Requirement R4, Part 4.2.2.2) should be required when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

   ☐ Yes
   ☐ No

   Comments:

2. Do you agree that the requirements of the proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2, including an implementation timetable and annual review of implementation status, should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading? For example, do you agree that a capital project is not required to be implemented by Requirement R4, Parts 4.2.2.1 and 4.2.2.2, even if the capital project is the only feasible action available to prevent the System from Cascading when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

   ☐ Yes
   ☐ No

   Comments:

3. Do you agree with the omission, as proposed in TPL-001-5 Requirement R4, Part 4.2, of a requirement similar to that of Requirement R2, Part 2.7, which states that the planned System shall continue to meet the performance requirements in Table 1 in subsequent Planning Assessments?

   ☐ Yes
   ☐ No

   Comments:

4. Do you agree with including Table 1 Footnote 13 a., "[a] single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, *e.g.*, sudden pressure relaying", and its limitation to only the specific single protective relay and not to other elements of the associated Protection System?

   ☐ Yes
   ☐ No

   Comments:

5. Do you agree with the inclusion of Table 1 Footnote 13 b. & c. stipulation, "which is not monitored or not reported", and that it conveys the expectation that the monitoring and reporting is sufficient to result in prompt remediation addressing the failure status of the associated equipment?

   ☐ Yes
   ☐ No

   Comments:

6. Do you agree with the inclusion of Table 1 Footnote 13 d., and that it, in conjunction with defined terms, identifies what constitutes all of the elements of, "A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices."?

   ☐ Yes
   ☐ No

   Comments:

7. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that modify which known outages shall be represented in System models from those "with a duration of at least six months" to those selected by the Planning Coordinator (PC)/Transmission Planner (TP) "in consultation with" their Reliability Coordinators (RCs).

   ☐ Yes
   ☐ No

   Comments:

8. Do you agree with omitting the Reliability Coordinator (RC) from the applicability of the TPL-001-5 standard given that Requirement R1, Part1.1.2 requires consultation between the TP/PC and the RC to determine which known outages to select for representation in System models?

   ☐ Yes
   ☐ No

   Comments:

9. FERC Order No. 786 Paragraphs 40-45 direct modification to address significant planned maintenance outages with durations less than 6 months in planning assessments. Are you aware of an existing standard/requirement, consistent with industry practice and applicability that requires review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in System models (TPL 001-4 Requirement R1 Part R1.1.2)?

☐ Yes
☐ No

Comments:

10. Do you agree with the 36 month implementation period to address all Requirements except for Requirement R4, Part 4.2, and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.

☐ Yes
☐ No

Comments:

11. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.2 and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.?

☐ Yes
☐ No

Comments:

12. In looking at all proposed recommendations from the standard drafting team, are the proposed changes a cost effective approach which meets the FERC directives? (*see* *Cost Effectiveness Background Document*)

☐ Yes
☐ No

Comments:

13. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

☐ Yes
☐ No

Comments:

14. Do you have any other general recommendations/considerations for the drafting team?

☐ Yes
☐ No

Comments:

Violation Risk Factor and Violation Severity Level Justifications

Project 2015-10 Single Points of Failure TPL-001

This document provides the standard drafting team's (SDT's) justification for assignment of violation risk factors (VRFs) and violation severity levels (VSLs) for Requirement R4 in Project 2015-10 and Single Points of Failure TPL-001. Each requirement is assigned a VRF and a VSL. These elements support the determination of an initial value range for the Base Penalty Amount regarding violations of requirements in FERC-approved Reliability Standards, as defined in the Electric Reliability Organizations (ERO) Sanction Guidelines. The SDT applied the following NERC criteria and FERC Guidelines when developing the VRFs and VSLs for the requirements.

NERC Criteria for Violation Risk Factors

High Risk Requirement

A requirement that, if violated, could directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly cause or contribute to Bulk Electric System instability, separation, or a cascading sequence of failures, or could place the Bulk Electric System at an unacceptable risk of instability, separation, or cascading failures, or could hinder restoration to a normal condition.

Medium Risk Requirement

A requirement that, if violated, could directly affect the electrical state or the capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System. However, violation of a medium risk requirement is unlikely to lead to Bulk Electric System instability, separation, or cascading failures; or, a requirement in a planning time frame that, if violated, could, under emergency, abnormal, or restorative conditions anticipated by the preparations, directly and adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System. However, violation of a medium risk requirement is unlikely, under emergency, abnormal, or restoration conditions anticipated by the preparations, to lead to Bulk Electric System instability, separation, or cascading failures, nor to hinder restoration to a normal condition.

Lower Risk Requirement

A requirement that is administrative in nature and a requirement that, if violated, would not be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor and control the Bulk Electric System; or, a requirement that is administrative in nature and a requirement in a planning time frame that, if violated, would not, under the emergency, abnormal, or restorative conditions anticipated by the preparations, be expected to adversely affect the electrical state or capability of the Bulk Electric System, or the ability to effectively monitor, control, or restore the Bulk Electric System.

FERC Guidelines for Violation Risk Factors

Guideline (1) – Consistency with the Conclusions of the Final Blackout Report

FERC seeks to ensure that VRFs assigned to Requirements of Reliability Standards in these identified areas appropriately reflect their historical critical impact on the reliability of the Bulk-Power System. In the VSL Order, FERC listed critical areas (from the Final Blackout Report) where violations could severely affect the reliability of the Bulk-Power System:

- Emergency operations
- Vegetation management
- Operator personnel training
- Protection systems and their coordination
- Operating tools and backup facilities
- Reactive power and voltage control
- System modeling and data exchange
- Communication protocol and facilities
- Requirements to determine equipment ratings
- Synchronized data recorders
- Clearer criteria for operationally critical facilities
- Appropriate use of transmission loading relief.

Guideline (2) – Consistency within a Reliability Standard

FERC expects a rational connection between the sub-Requirement VRF assignments and the main Requirement VRF assignment.

Guideline (3) – Consistency among Reliability Standards

FERC expects the assignment of VRFs corresponding to Requirements that address similar reliability goals in different Reliability Standards would be treated comparably.

Guideline (4) – Consistency with NERC's Definition of the Violation Risk Factor Level

Guideline (4) was developed to evaluate whether the assignment of a particular VRF level conforms to NERC's definition of that risk level.

Guideline (5) – Treatment of Requirements that Co-mingle More Than One Obligation

Where a single Requirement co-mingles a higher risk reliability objective and a lesser risk reliability objective, the VRF assignment for such Requirements must not be watered down to reflect the lower risk level associated with the less important objective of the Reliability Standard.

NERC Criteria for Violation Severity Levels

VSLs define the degree to which compliance with a requirement was not achieved. Each requirement must have at least one VSL. While it is preferable to have four VSLs for each requirement, some requirements do not have multiple "degrees" of noncompliant performance and may have only one, two, or three VSLs.

VSLs should be based on NERC's overarching criteria shown in the table below:

Lower VSL	Moderate VSL	High VSL	Severe VSL
The performance or product measured almost meets the full intent of the requirement.	The performance or product measured meets the majority of the intent of the requirement.	The performance or product measured does not meet the majority of the intent of the requirement, but does meet some of the intent.	The performance or product measured does not substantively meet the intent of the requirement.

FERC Order of Violation Severity Levels

The FERC VSL guidelines are presented below, followed by an analysis of whether the VSLs proposed for each requirement in the standard meet the FERC Guidelines for assessing VSLs:

Guideline (1) – Violation Severity Level Assignments Should Not Have the Unintended Consequence of Lowering the Current Level of Compliance

Compare the VSLs to any prior levels of non-compliance and avoid significant changes that may encourage a lower level of compliance than was required when levels of non-compliance were used.

Guideline (2) – Violation Severity Level Assignments Should Ensure Uniformity and Consistency in the Determination of Penalties

A violation of a "binary" type requirement must be a "Severe" VSL.

Do not use ambiguous terms such as "minor" and "significant" to describe noncompliant performance.

Guideline (3) – Violation Severity Level Assignment Should Be Consistent with the Corresponding Requirement

VSLs should not expand on what is required in the requirement.

Guideline (4) – Violation Severity Level Assignment Should Be Based on A Single Violation, Not on A Cumulative Number of Violations

Unless otherwise stated in the requirement, each instance of non-compliance with a requirement is a separate violation. Section 4 of the Sanction Guidelines states that assessing penalties on a per violation per day basis is the “default” for penalty calculations.

VRF Justification for TPL-001-5, Requirement R1

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R1

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R2

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R2

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R3

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R3

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R4

The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R4

The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R5
The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R5
The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R6
The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R6
The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R7
The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R7
The VSL did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VRF Justification for TPL-001-5, Requirement R8
The VRF did not change from the previously FERC approved TPL-001-4 Reliability Standard.

VSL Justification for TPL-001-5, Requirement R8

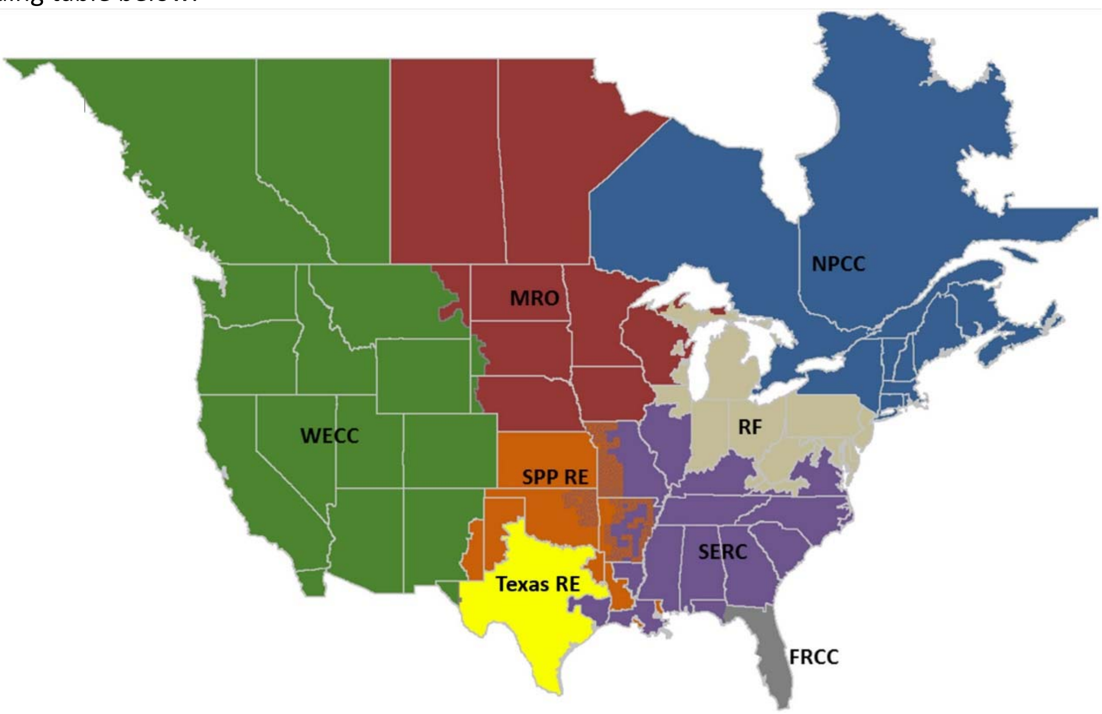
Preface

The North American Electric Reliability Corporation (NERC) is a not-for-profit international regulatory authority whose mission is to assure the reliability and security of the bulk power system (BPS) in North America. NERC develops and enforces Reliability Standards; annually assesses seasonal and long-term reliability; monitors the BPS through system awareness; and educates, trains, and certifies industry personnel. NERC's area of responsibility spans the continental United States, Canada, and the northern portion of Baja California, Mexico. NERC is the Electric Reliability Organization (ERO) for North America, subject to oversight by the Federal Energy Regulatory Commission (FERC) and governmental authorities in Canada. NERC's jurisdiction includes users, owners, and operators of the BPS, which serves more than 334 million people.

The North American BPS is divided into eight Regional Entity (RE) boundaries as shown in the map and corresponding table below.



The North American BPS is divided into eight RE boundaries. The highlighted areas denote overlap as some load-serving entities participate in one Region while associated transmission owners/operators participate in another.

FRCC	Florida Reliability Coordinating Council
MRO	Midwest Reliability Organization
NPCC	Northeast Power Coordinating Council
RF	ReliabilityFirst
SERC	SERC Reliability Corporation
SPP RE	Southwest Power Pool Regional Entity
Texas RE	Texas Reliability Entity
WECC	Western Electricity Coordinating Council

Executive Summary

Project 2015-10 Technical Rationale provides the background and rationale for proposed revisions to Reliability Standard TPL-001-4. The proposed revisions address reliability issues concerning the study of single points of failure (SPF) on Protection Systems from FERC Order No. 754, directives from FERC Order No. 786 regarding planned maintenance outages and spare equipment strategy for stability analysis, and replaces references to the MOD-010 and MOD-012 standards with the MOD-032 Reliability Standard.

Key Concepts of FERC Order No. 754

The Standards Development Team (SDT) took into account the recommendations for modifying NERC Reliability Standard TPL-001-4 identified in the SPCS and SAMS report titled *Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request*. Proposed revisions changes extreme event (3-phase fault) to include a fault and failure of a non-redundant component of a Protection System. In "Table 1 – Steady State and Stability Performance Extreme Events," breaker failure and failure of a non-redundant component of a Protection System are differentiated. The SDT recognizes that sequence of Protection System action leading to Delayed Clearing may be quite different between the two causalities. Footnote 13 expands Protection System components to be considered for Category P5 and for extreme events 2e through 2h.

Key Concepts of FERC Order No. 786

The SDT considered the Commission's concern that the outages of significant facilities less than six months could be overlooked for planning purposes, Category P3 and P6 do not sufficiently cover planned maintenance outages, and Near-Term Transmission Planning Horizon requires annual assessments using Year One or year two, and year five, and known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon. Proposed revisions remove the six month outage duration and replace it with consultation with the Reliability Coordinator (RC) to identify known outages of significant facilities that cannot be readily managed through near-term operational coordination processes. Proposed revisions includes stability study for long lead equipment that does not have a spare.

Summary of proposed revisions:

- Requirement R1 – Updated for MOD-032-1 standard.
- Requirement R1, Part 1.1.2 – Modified how known outages are selected for study.
- Requirement R2, Part 2.1.3 – Modified the P1 contingency events simulated (steady state) for known outages.
- Requirement R2, Part 2.4.3 – Added model conditions for stability analysis of P1 events for known outages.
- Requirement R2, Part 2.4.5 – Added stability analysis requirement for long lead time equipment unavailability.
- Requirement R4, Part 4.2 – Added documentation requirement if Cascading observed given 3-phase fault SPF.
- Table 1 – Modified Category P5 event to include SPF.
- Table 1 – Modified Extreme Events, Stability column to differentiate SPF from stuck breaker.
- Table 1 – Modified Footnote 13 to specify SPF.

Introduction

NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) is being modified to address reliability issues and standard modification directives contained in FERC Order No. 754[1] and FERC Order No. 786.[2] Proposed Reliability Standard TPL-001-5 revises the TPL-001 standard to address the reliability risks posed by SPF on Protection Systems.

Background

FERC Order No. 754

FERC Order No. 754 directed NERC to study the reliability risk associated with single points of failure (SPF) in Protection Systems. The NERC System Protection and Control Subcommittee (SPCS) and the System Analysis and Modelling Subcommittee (SAMS) conducted an assessment of Protection System SPF in response to FERC Order 754, including analysis of data collected pursuant to a request for data or information under Section 1600 of the NERC Rules of Procedure. The SPCS and SAMS report titled *Order No. 754 Assessment of Protection System Single Points of Failure Based on the Section 1600 Data Request* provides extensive general discussion about the reliability risks associated with a SPF. Available

FERC Order No. 786

In Order No. 786, FERC directed NERC to address two issues. The first issue is the concern that the six month outage duration threshold could exclude planned maintenance outages of significant facilities from future planning assessments. FERC directed NERC to modify TPL-001-4 to address this concern. The second issue involves adding clarity regarding dynamic assessment of outages of critical long lead time equipment, consistent with the entity's spare equipment strategy. FERC directed NERC to consider this issue upon its next review of TPL-001-4. The NERC SAMS developed a white paper documenting the technical analysis conducted by SAMS to address the two directives contained in the FERC Order 786. The white paper provides extensive general discussion regarding the directives.

Section 1: Single Points of Failure on Protection Systems (FERC Order No. 754)

NERC Advisory

On March 30, 2009, NERC issued an advisory[3] report notifying the industry that a SPF issue had caused three significant system disturbances in 5 years.

Transmission Owners, Generation Owners, and Distribution Providers owning Protection Systems installed on the Bulk Electric System were advised to address SPF on their Protection Systems when identified in routine system evaluations to prevent N-1 transmission system contingencies from evolving into more severe or even extreme events.

These entities were additionally advised to begin preparing an estimate of the resource commitment required to review, re-engineer, and develop a workable outage and construction schedule to address SPF on their Protection Systems.

FERC Order No. 754

In Order No. 754 Paragraph 20, FERC directed NERC to "to make an informational filing within six months of the date of the issuance of this Final Rule explaining whether there is a further system protection issue that needs to be addressed and, if so, what forum and process should be used to address that issue and what priority it should be accorded relative to other reliability initiatives planned by NERC."

FERC Technical Conference

A FERC technical conference concerning the Commission's Order 754 titled Staff Meeting on Single Points of Failure on Protection Systems was held on October 24-25, 2011 at FERC in Washington, DC.

At the Technical Conference, the attendees discussed the SPF issue and narrowed their concerns into four consensus points:

- The concern with assessment of SPF is a performance-based issue, not a full redundancy issue.
- The existing approved standards address assessments of SPF.
- Assessments of SPF of non-redundant primary protection (including backup) systems need to be sufficiently comprehensive.
- Lack of sufficiently comprehensive assessments of non-redundant primary Protection Systems is a reliability concern.

Joint SPCS-SAMS Report

One outcome of the FERC Technical Conference was that NERC would conduct a data collection effort to provide a broad factual foundation that could aid in assessing the reliability risks posed by SPF. The NERC Board of Trustees approved the request for data or information under Section 1600 of the NERC Rules of Procedure ("Order No. 754 Data Request") on August 16, 2012.

In September 2015, SPCS and SAMS issued a report to the NERC PC/OC, summarizing the information collected under the Order No. 754 Data Request. The assessment confirmed the existence of a reliability risk associated

[3] *See Industry Advisory: Single Point of Failure*

with SPF in Protection Systems that warrants further action. To address this risk, the SPCS and the SAMS considered a variety of alternatives and concluded that the most appropriate recommendation that aligns with FERC Order 754 directives and maximizes reliability of Protection System performance is to modify NERC Reliability Standard TPL-001-4 (Transmission System Planning Performance Requirements) through the NERC standards development process.

The report recommendations, as well as how they have been addressed in proposed TPL-001-5 by the Project 2015-10 standard drafting team are summarized in the following section.

Revisions to TPL-001-4

Table 1-Footnote 13

The SPCS/SAMS report recommended replacing “relay” with “component of a Protection System” in the Table 1 P5 event and replace Footnote 13 in TPL-001-4 with the following alternate wording:

> The components from the definition of ’Protection System‘ for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

This revision to Footnote 13 clarifies the components of the Protection System that must be considered when simulating Delayed Fault Clearing due to the failure of a non-redundant component of a Protection System. This consideration is intended to account for:

- failed non-redundant components of a Protection System that may impact one or more Protection Systems;
- the duration that faults remain energized until Delayed Fault Clearing, and;
- additional system equipment removed from service following fault clearing depending upon the specific failed non-redundant component of a Protection System.

The SPCS/SAMS report described voltage or current sensing devices as having a lower level of risk of failure to trip due to robustness and likelihood to actually cause tripping upon failure. Therefore, these components of a Protection System are omitted from Footnote 13.

Noting that Requirements R3.3.1 and R4.3.1 require simulation of Protection System action, the drafting team sought to limit the scope of Footnote 13, item 1 with respect to protective relays that may be non-redundant components of a Protection System. Specifically, Footnote 13 limits single protective relays that may be a SPF to those which respond to electrical quantities and are used for primary protection resulting in Normal Clearing. An SPF in a single protective relay that is a non-redundant component of a Protection System may result in the primary Protection System failing to properly operate, leading to Delayed Fault Clearing performed by backup protective relays and/or overlapping zonal protection. Conversely, the drafting team did not include backup protective relays in the scope of Footnote 13, item 1 given that an SPF in a single protective relay used for backup protection will not affect primary protection resulting in Normal Clearing.

The drafting team recognizes that Bulk Electric System (BES) Elements are predominantly protected by relays which respond to electrical quantities. However, in some Protection System designs, non-redundant single protective relays which respond to electrical quantities may be redundant to protective relays that do not respond to electrical quantities. For example, an independent differential relay and independent sudden pressure relay may protect the same transformer from faults inside the transformer tank. In this example, the differential relay responds to electrical quantities, while the sudden pressure relay does not. While the transformer differential relay may be an SPF, an internal transformer tank fault may not lead to Delayed Clearing given the sudden pressure protection. Subsequently, the P5 event for a single phase-to-ground (line-to-ground) fault in the transformer tank need not be simulated for Delayed Fault Clearing due to the SPF of the transformer differential relay, but should be simulated for the sudden pressure relay clearing time, which may not be delayed. However, care must be taken when evaluating protective relays which respond to electrical quantities in combination with protective relays which do not respond to electrical quantities; in this same example, faults that occurred outside of the transformer tank given the SPF of the non-redundant transformer differential relay would be unaffected by the presence of the sudden pressure relay and would lead to delayed clearing, necessitating its assessment as a P5 event.

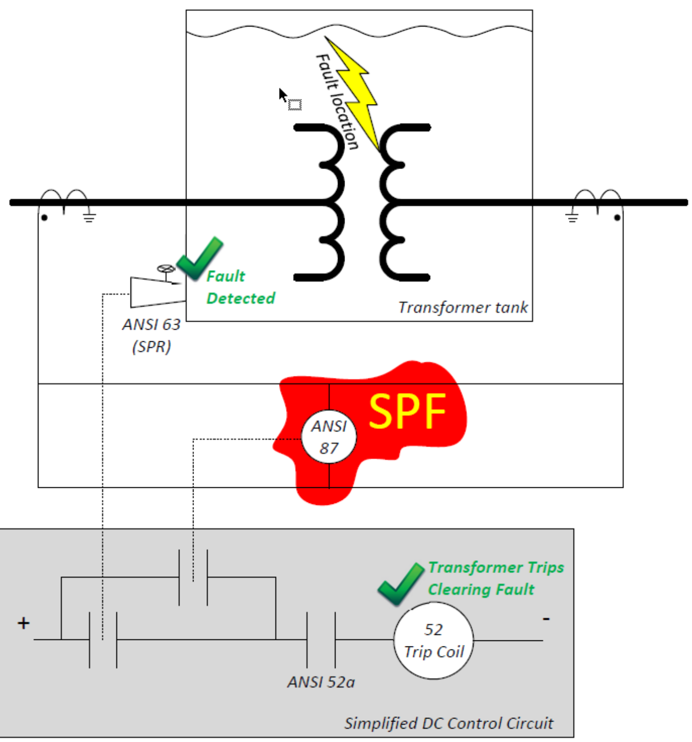

Figure 2.1: Internal Transformer Tank Fault with Sudden Pressure Protection and failed Transformer Differential Relay

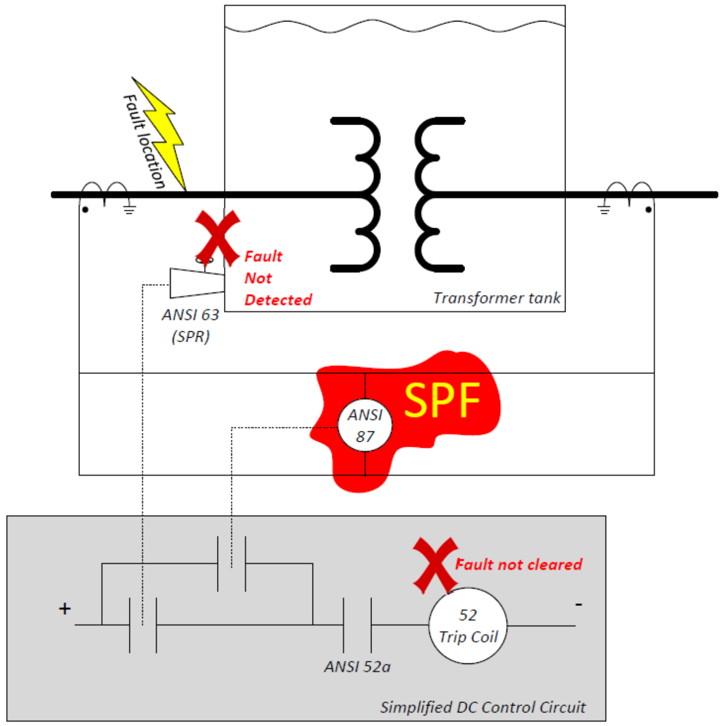

Figure 2.2: External Transformer Tank Fault with Sudden Pressure Protection and failed Transformer Differential Relay

Given the increasing importance of communication-aided Protection Systems (e.g., pilot protection schemes, direct transfer tripping schemes, permissive transfer tripping schemes, line differential relaying schemes, etc.), the proper operation of the communication system must be considered when considering potential SPF components of Protection Systems. The drafting team augmented the SAMS/SPCS recommendations to include reference to the subset of communication systems that are part of a communication-aided Protection System, necessary where the performance of that Protection System is required to achieve Transmission System Planning (TPL) Performance Requirements, enumerated in Table 1 of TPL-001-4. In other words, a communication-aided Protection System that may experience an SPF, causing it to operate improperly or not at all, must be considered as part of non-redundancy. The drafting team concluded that the failure of communication-aided Protection Systems may take many forms; however, by alarming and monitoring these systems, the overall risk of impact to the Bulk Electric System is reduced to an acceptable level. Most new Protection Systems deployed in the industry include communication-aided protection with component and communication failure alarms monitored at centralized Control Centers. This alarm monitoring is similar to the requirement associated with station DC supplies. Therefore, this requirement is more applicable to legacy systems that need communication-aided Protection Systems to meet performance requirements of the TPL standards.

Requirement R4 Part 4.2 Extreme Events

Analysis of the data collected under the Order No. 754 Data Request demonstrates the existence of a reliability risk associated with SPF in Protection Systems. Further, while the analysis shows that the risk from SPF is not an endemic problem and instances of SPF exposure are lower on higher voltage systems, the risk is sufficient to warrant further action. Risk-based assessment should be used to identify Protection Systems of concern (i.e., locations on the BES where there is a susceptibility to cascading if a Protection System component SPF exists). Given the risk to BES reliability, additional emphasis in planning studies should be placed on assessment of three-phase faults involving Protection System SPF. This concern (the study of Protection System SPF) is appropriately addressed as an extreme event in TPL-001-4, Requirement R4, Part 4.2. While less probable than single-phase-to-ground faults, three-phase faults typically initiate as single-phase-to-ground and often evolve into three-phase faults, leading to Delayed Fault Clearing scenarios more severe than the Table 1 P5 event. Therefore, TPL-001-4, Requirement R4, Part 4.5, which specifies that an evaluation of possible mitigating actions be conducted if analysis concludes there is cascading caused by the occurrence of this extreme event, is inadequate to address the risk of Protection System component SPF to the reliability of the BES. To address this concern the drafting team has modified Requirement 4 part 4.2.2 to require additional evaluation and documentation of possible actions designed to prevent the system from cascading for extreme events 2e-2h listed from the stability column of Table 1. The additional documentation shall list System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation. The analysis shall be reviewed in subsequent annual Planning Assessments for continued validity and implementation status. Thus, the drafting team has maintained the three-phase-fault given a Protection System component SPF as an extreme event, but modified Requirement R4, Part 4.2.2 to require additional evaluation and documentation of possible actions, including a timetable of implementation, designed to prevent the system from Cascading. This consideration is intended to account for:

- failed non-redundant components of a Protection System that may impact one or more Protection Systems;
- the duration that faults remain energized until Delayed Fault Clearing, and;
- Additional system equipment removed from service following fault clearing depending upon the specific failed non-redundant component of a Protection System.

Footnote 13 provides the attributes of the specific non-redundant Protection System components that the entity shall consider for evaluation.

Section 2: FERC Order No. 786 Directives

Background

In addition to addressing reliability issues involving SPF on Protection Systems, proposed Reliability Standard TPL-001-5 revises the TPL-001 standard to address two directives from FERC Order No. 786.

Order No. 786 P. 40: Maintenance outages in the Planning Horizon

FERC Order No. 786, Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments. Order No. 786 provides the following considerations:

- Planned maintenance outages less than six months may result in impacts during peak and off-peak periods;
- Planned outages during those times should be considered to allow for a single element to be taken out of service without compromising the ability to meet demand;
- Criticality of elements taken out for maintenance could result in N-1 outage and loss of non-consequential load or impact to reliability;
- Planned outages are not “hypothetical outages” and should not be treated as multiple contingencies in the planning standard (should be addressed in N-0 base case);
- Relying on Category P3 and P6 is not sufficient and does not cover maintenance outages;
- The Near-Term Transmission Planning Horizon requires annual assessments using Year One or year two and year five. Known planned facility outages of less than six months should be addressed so long as their planned start times and durations may be anticipated as occurring for some period of time during the planning time horizon.

NERC SAMS Whitepaper Recommendations

To address this directive, the NERC SAMS recommended modifications to NERC Reliability Standards IRO-017-1 and TPL-001-4. The SAMS recommended that IRO-017-1 be used as the vehicle to assure that all types of known scheduled outages are being reviewed and coordinated to mitigate reliability impact as the most cost-effective means to address the intent of the NERC directive. The coordination process developed pursuant to IRO-017-1, Requirement R1 should be used to direct how all known scheduled outages are reviewed and the actions that must be taken. The SAMS recommended that following objectives should be added to R1:

- Describe how the review of known scheduled outages by the RC, PC, TO, and TP will be integrated into transmission plan development.
- Describe whether, how, and which known scheduled outages should be included in the Planning Assessment for the Near-Term Transmission Planning Horizon required by TPL-001-4.
- Describe how emerging challenges and the inability to schedule outages will be communicated from the TO and RC to the TP and PC to be addressed in a future Corrective Action Plan pursuant to TPL-001-4.

The NERC SAMS also recommended modifying TPL-001-4, Requirement 1.1.2 by removing “with duration of at least six months” and adding language referencing the outage coordination process developed in IRO-017-1, Requirement R1 as described above.

Revisions to TPL-001-4

Requirement R1 Part 1.1.2

The drafting team modified Requirement 1.1.2 consistent with FERC's directive and included necessary consultation with the Reliability Coordinator. This consultation is expected to assist the Transmission Planner and Planning Coordinator select known outages that are relevant, not hypothetical, and have a credible likelihood of being concurrent.

The change to Requirement 1, Part 1.1.2 eliminates the specified six month outage duration and provides the opportunity for the Reliability Coordinator to assist the Planning Coordinator and/or Transmission Planner to determine which known outages, if any, need to be considered in the Planning Assessment for the Near-Term. This change is for coordination of known outages beyond the Operations Planning time horizon.

Order No. 786 P 89: Dynamic assessment of outages of critical long lead time equipment

In paragraph 89 of Order No. 786, FERC stated:

> The spare equipment strategy for steady state analysis under Reliability Standard TPL-001-4, Requirement R2, Part 2.1.5 requires that steady state studies be performed for the P0, P1 and P2 categories identified in Table 1 with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment. The Commission believes that a similar spare equipment strategy for stability analysis should exist that requires studies to be performed for P0, P1 and P2 categories with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment.

FERC did not direct a change but did direct NERC to consider this issue upon the next review cycle of TPL-001-4. The Project 2015-10 Standard Authorization Request included this issue within the scope of this project.

NERC SAMS Whitepaper Recommendations

The NERC SAMS considered the following key points related to FERC's Paragraph 89 guidance:

- Removal of Elements in the Planning Assessment for spare equipment strategy is only applicable for those Elements that have "a lead time of one year or more."
- Each long-lead time Element that is removed from service creates a new operating condition considered the "normal" (P0) condition for Table 1. The applicable contingencies will be studied with that Element removed from service in the pre-contingency state for stability analysis. For example, if a long-lead time transformer does not have a spare, it would be studied as a P1.3 event. Since P0 does not include an Event, P0 does not and should not be included in the stability analysis section for long-lead time Elements not included as part of a spare equipment strategy.
- System adjustments may need to be made to the power flow base case to accurately reflect reasonable and expected operating conditions with that Element removed from service in the pre-contingency (P0) operating state.
- TPL-001-4, Requirement R4.1.1, related to P1 Events, requires that no generating unit pull out of synchronism. The outage of a long-lead time Element followed by a P1 contingency should not result in a generating unit losing synchronism.
- TPL-001-4, Requirement R4.1.2, related to P2 Events, allows for generating units to pull out of synchronism. The outage of a long-lead time Element followed by a P2 contingency should not result in

tripping of any Transmission System Elements other than the generating unit and its directly connected Facilities.

The NERC SAMS white paper contains the flowing recommendations for stability analysis for long lead time Elements not included as part of a spare equipment strategy:

- The outage of long lead time Elements has an equally important impact from a stability standpoint as it does from a steady-state standpoint.
- The Planning Coordinator and Transmission Planner must demonstrate that they have met the TPL-001-4 performance criteria for specified contingency events and contingency combinations thereof as per Table 1. This should include long lead time outages that can occur for equipment that does not have a spare equipment strategy.
- TPL-001-4, Requirement R4.1.1 requires that no generating unit pull out of synchronism, while R4.1.2 allows for generating units to pull out of synchronism so long as the resulting instability does not result in tripping of any Transmission System Elements other than the generating unit and its directly connected Facilities. The outage of a long lead time Element followed by a P1 contingency should not result in a generating unit losing synchronism.
- While the P2 contingency allows for individual generating unit instability, the Transmission Planner and Planning Coordinator must ensure that this instability does not result in tripping of any Transmission System Elements other than the generating unit and its directly connected Facilities and therefore should include P2 contingencies event.

Revisions to TPL-001-4

Requirement R2 Part 2.4.5

Consistent with FERC's Order No. 786 guidance and the SAMS recommendations, the Project 2015-10 standard drafting team revised TPL-001-4 Requirement R2 Part 2.4.5 to add a similar requirement for stability analysis. The change to Requirement R2, Part 2.4.5, which includes similar language to that used for the steady-state analysis under R2.1.5, adds clarity that the outage of long lead time Elements has an equally important impact from a stability standpoint as it does from a steady-state standpoint and should be assessed commensurate with an entity's spare equipment strategy.

Section 3: Applicability

The requirements remain applicable to the Planning Coordinator and Transmission Planner. Coordination and cooperation between operating and planning entities in concert with asset owners will be required to implement the standard requirements. The planning and protection engineers that will need to conduct the studies and submit the data may be working for different companies or business units, and time will be required to accommodate the development of processes and data flow that cross company or business unit lines.

Generator Owners, Transmission Owners, and Distribution Providers are required to evaluate the Protection System(s) for locations on the system where a failure of a non-redundant Protection System component could result in a potential reliability risk. These entities must provide this information, as well as resulting fault clearing times, to Transmission Planners for proper study.

Project 2015-10 Single Points of Failure TPL-001

Cost Effectiveness

Known Outages FERC Order No. 786

FERC Order No. 786 Paragraph 40 directs a change to address the concern that the six month threshold could exclude planned maintenance outages of significant facilities from future planning assessments. See paragraphs 33-45 for the discussion on planned maintenance outages.

Overview of Commission Determination (Paragraphs 40-45)

The commission stated in Order No. 786 Paragraph 41:

- For the reasons discussed below, the Commission finds that planned maintenance outages of less than six months in duration may result in relevant impacts during one or both of the seasonal off-peak periods.
- Prudent transmission planning should consider maintenance outages at those load levels when planned outages are performed to allow for a single element to be taken out of service for maintenance without compromising the ability of the system to meet demand without loss of load.
- We agree with commenters such as MISO and ATCLLC that certain elements may be so critical that, when taken out of service for system maintenance or to facilitate a new capital project, a subsequent unplanned outage initiated by a single-event could result in the loss of non-consequential load or may have a detrimental impact to the bulk electric system reliability.
- A properly planned transmission system should ensure the known, planned removal of facilities (i.e., generation, transmission or protection system facilities) for maintenance purposes without the loss of non-consequential load or detrimental impacts to system reliability such as cascading, voltage instability or uncontrolled islanding.

The Commission Disagreed with the following:

- Order No. 786 Paragraph 44: The existing TPL-001-4 for Category P3 covers generator maintenance outages, Category P6 covers transmission maintenance outages.
- Order No. 786 Paragraph 45: Planned outages of less than one year in duration should be addressed operationally by determining new operating limits and taking other actions to mitigate the planned outage.
- Order No. 786 Paragraph 45: Planned outages of less than six months is unnecessary since…10 year time frame.

Options Considered By Standard Drafting Team to Satisfy FERC Order

The following options considered by the NERC Standard Drafting Team for Requirement R1 Part 1.1.2 include (refer to SAMS recommendations):

Option 1 (SAMS recommendation from Order No. 754 Report):

Requirement R1, Part 1.1.2 Known outage(s) of generation or Transmission Facility(ies) ~~with a duration of at least six months.~~ as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and R. 2.4.3.

Option 2

Requirement R1, Part 1.1.2 Known outage(s) of generation or Transmission Facility(ies) ~~with a duration of at least six months.~~

Option 3

Requirement R1, Part 1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of at least ~~six months~~ three months.

Option 4

Requirement R1, Part 1.1.2 Known outages(s) of generation or Transmission Facility(ies) with duration of at least ~~six~~ four months and any other significant planned outages of generation or Transmission Facility(ies) with a duration of less than four months that are expected to produce more severe System impacts on its portion of the BES. These outage coordinations are required to be performed for the season/load-levels that outages are normally planned at and shall be performed only in the Near-Term Transmission Planning Horizon.

Standard Drafting Team Proposal for Requirement R1 Part 1.1.2

The following is the option (Option 1) selected by the standard drafting team which satisfies the FERC Order. The following 1 option selected and in general aligns with the SAMS recommendation.

Option 1 (SAMS recommendation from Order No. 754 Report):

Requirement R1, Part 1.1.2 Known outage(s) of generation or Transmission Facility(ies) ~~with a duration of at least six months.~~ as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and R. 2.4.3.

Spare Equipment Strategy FERC Order No. 786

FERC Order No. 786 Paragraph 89 the Commission believes that a similar spare equipment strategy for stability analysis should exist that requires studies to be performed for P0, P1 and P2 categories with the conditions that the system is expected to experience during the possible unavailability of the long lead time equipment. See Paragraph 85 through 89 of Order No. 786 for a discussion on spare equipment strategy.

Overview of Commission Determination (Order No. 786 Paragraphs 88-89)

The commission stated in Order No. 786:

- Order No. 786 Paragraph 88: The commission agrees that NERC has met the spare equipment strategy directive for steady state analysis under TPL-001-4 R2, Part 2.1.5.
- Order No. 786 Paragraph 88: The Commission finds that a spare equipment strategy for stability analysis is not addressed under category P6.
- Order No. 786 Paragraph 89: The commission is not persuaded by the explanation of NERC and others that a similar spare equipment strategy for stability analysis would cause unjustified burden because stability analysis is already required under category P6.

Options Considered By Standard Drafting Team to Satisfy FERC Order No. 786

Since the FERC Order in Paragraph 89 was very specific, there was only one option considered by the standard drafting team that met the requirements of the FERC Order Paragraph 89 request.

Option 1 Addition of Part 2.4.5

Requirement R1, Part 1.1.2 When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be ~~studied~~ assessed. ~~The studies~~ Based upon this assessment, an analysis shall be performed for the selected P1 and P2 ~~categories~~ category events identified in Table 1 for which the unavailability ~~with the conditions that the System~~ is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

Single Point of Failure of the Protection System

Based on Order No. 754 directive of September 15, 2011; NERC informational filing dated March 15, 2012; Section 1600 data request; and the 2nd NERC informational filing dated October 30, 2015, the SPCS/SAMS report to address the concern of Single Point Of Failure of a protection system:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace "relay" with "component of a Protection System," and
  - Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase "or a relay failure" from items a, b, c, and d to create distinct events only for stuck breakers.
  - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure" with "a component failure of a Protection System."

- Replace footnote 13 in TPL-001-4 with, "The components from the definition of "Protection System" for the purposes of this standard include (1) protective relays that respond to electrical quantities, (2) single – station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and (3) DC control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices."
- Modify TPL-001-4 (Part 4.5) so that extreme event assessments must include evaluation of the three phase faults the described component failures of a Protection System that produce the more severe system impacts. For example, add a new second sentence that reads "[t]he list shall consider each of the extreme events in Table 1 – Steady State & Stability Performance Extreme Events; Stability column item number 2."

Options Considered By Standard Drafting Team to Satisfy FERC Order

Since some of the recommendations from the SPCS and SAMS report were so specific, there were no other options considered for the following:

- For Table 1 – Steady State & Stability Performance Planning Events, Category P5:
  - Replace "relay" with "component of a Protection System," and
  - Add superscript "13" to reference footnote 13 for the replaced term under the "Category" column.
- For Table 1 – Steady State & Stability Performance Extreme Events, under the Stability column, No. 2:
  - Remove the phrase "or a relay failure" from items a, b, c, and d to create distinct events only for stuck breakers.
  - Append four new events for the same items a, b, c, and d in the above bulleted item to create distinct events replacing "a relay failure" with "a component failure of a Protection System."

Different options were considered for footnote 13 language. These options are:

Option 1 Footnote 13

The Standard Drafting Team for TPL-001 considered revising footnote 13 to include all five components. In the NERC glossary of terms, a Protection System include five components. These are:

Protection System –

- Protective relays which respond to electrical quantities,
- Communications systems necessary for correct operation of protective functions
- Voltage and current sensing devices providing inputs to protective relays,

- Station dc supply associated with protective functions (including station batteries, battery chargers, and non-battery-based dc supply), and
- Control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Option 2 Footnote 13

The second option was to have footnote 13 list four of the five components of a protection system but limit *"communications systems"* to only those that are not monitored or alarmed. The following is language for Footnote 13[1]:

13. For the purposes of P5 of this standard, components of a Protection System include the following:

  a. A single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying;

  b. A single communications system, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported;

  c. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit;

  ~~a.~~d. A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.

Option 3 Footnote 13

a. The components from the definition of Protection System" for the purposes of this standard include:
b. protective relays that respond to electrical quantities,
c. single – station DC supply that is not monitored for both low voltage and open circuit, with alarms centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated), and
d. control circuitry associated with protective functions through the trip coil(s) of the circuit breakers or other interrupting devices.

Standard Drafting Team Proposal for Table 1 Footnote 13:

The Standard Drafting Team selected Option 2 which expands Protection System components to be considered to determine the impact to the BES if that component failed when a fault occurs.

[1] Failure of voltage and current sensing device would result in a breaker operation without a fault which was considered not a reliability risk to the BES.

Option 2 Footnote 13

The second option was to have footnote 13 list four of the five components of a protection system but limit *"communications systems"* to only those that are not monitored or alarmed. The following is language for Footnote 13[2]:

For the purposes of P5 of this standard, components of a Protection System include the following:

a. A single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying;

b. A single communications system, necessary for correct operation of a communication-aided protection scheme required for Normal Clearing, which is not monitored or not reported;

c. A single dc supply associated with protective functions, and that single station dc supply is not monitored or not reported for both low voltage and open circuit;

~~a.~~d. A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.

Addition of Corrective Action Plan for Extreme Event Three – Phase Faults:

The SPCS and SAMS report for Order No. 754 recommended that three phase faults involving single points of failure of a protection system be addressed. Additionally, the standard drafting team recognized that the Order No. 754 data requirement collected data for a three-phase fault and not a single-line-ground fault. The Order No. 754 data collection and report indicated a risk to the BES for three phase faults involving single points of failure of a protection system.

Options Considered By Standard Drafting Team to Satisfy FERC Order

Option 1:

Do not add anything for extreme event three-phase faults with protection failure.

Option 2:

Addition of Requirement 4 Part 4.2.1 and 4.2.2 as follows:

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.2.1. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

[2] Failure of voltage and current sensing device would result in a breaker operation without a fault which was considered not a reliability risk to the BES.

4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation~~List System deficiencies, the associated actions, and an associated timetable for implementation needed to prevent the System from Cascading.~~

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

Standard Drafting Team Proposal

The standard drafting team selected Option 2 which was to add a requirement to require a Corrective Action Plan if a three-phase fault followed by a protection failure causes cascading.

Option 2:

4.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R4, Part 4.5.

4.2.1. If the analysis concludes there is Cascading caused by the occurrence of extreme events, excluding extreme events 2e-2h in the stability column, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

4.2.2. If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, an evaluation of possible actions designed to prevent the System from Cascading shall:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading, and the associated timetable for implementation~~List System deficiencies, the associated actions, and an associated timetable for implementation needed to prevent the System from Cascading.~~

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status.

Reminder

Project 2015-10 Single Points of Failure

Initial Ballot and Non-binding Poll Open through October 23, 2017

Now Available

An initial ballot for **TPL-001-5 – Transmission System Planning Performance Requirements** and non-binding poll of the associated Violation Risk Factors and Violation Severity Levels are open through **8 p.m. Eastern, Monday, October 23, 2017**

Balloting
Members of the ballot pools associated with this project can log in and submit their votes by accessing the Standards Balloting and Commenting System (SBS) here. If you experience any difficulties in navigating the SBS, contact Wendy Muller.

- *If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).*
- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps
The ballot results will be announced and posted on the project page. The drafting team will review all responses received during the comment period and determine the next steps of the project.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer, Latrice Harkness (via email) or at (404) 446-9728.

Standards Announcement

Project 2015-10 Single Points of Failure

Formal Comment Period Open through October 23, 2017
Ballot Pools Forming through October 6, 2017

Now Available

A 45-day formal comment period for **TPL-001-5 – Transmission System Planning Performance Requirements** is open through **8 p.m. Eastern, Monday, October 23, 2017.**

Commenting

Use the Standards Balloting and Commenting System (SBS) to submit comments. If you experience any difficulties navigating the SBS, contact Wendy Muller. An unofficial Word version of the comment form is posted on the project page.

Ballot Pools

Ballot pools are being formed through **8 p.m. Eastern, Friday, October 6, 2017.** Registered Ballot Body members can join the ballot pools here.

If you are having difficulty accessing the SBS due to a forgotten password, incorrect credential error messages, or system lock-out, contact NERC IT support directly at https://support.nerc.net/ (Monday – Friday, 8 a.m. - 5 p.m. Eastern).

- *Passwords expire every **6 months** and must be reset.*
- *The SBS **is not** supported for use on mobile devices.*
- *Please be mindful of ballot and comment period closing dates. We ask to **allow at least 48 hours** for NERC support staff to assist with inquiries. Therefore, it is recommended that users try logging into their SBS accounts **prior to the last day** of a comment/ballot period.*

Next Steps

An initial ballot for the standard and non-binding poll of the associated Violation Risk Factors and Violation Severity Levels will be conducted **October 13-23, 2017**.

For information on the Standards Development Process, refer to the Standard Processes Manual.

For more information or assistance, contact Senior Standards Developer, Latrice Harkness or at (404) 446-9728.

Comment Report

Project Name:	Project 2015-10 Single Points of Failure | TPL-001-5
Comment Period Start Date:	9/8/2017
Comment Period End Date:	10/23/2017
Associated Ballots:	2015-10 Single Points of Failure TPL-001-5 IN 1 ST

There were 70 sets of responses, including comments from approximately 192 different people from approximately 118 companies representing 10 of the Industry Segments as shown in the table on the following pages.

Questions

1. Do you agree that an associated timetable for implementation of actions needed to prevent the System from Cascading (TPL-001-5 Requirement R4, Part 4.2.2.1) and an annual review of implementation status (TPL-001-5 Requirement R4, Part 4.2.2.2) should be required when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

2. Do you agree that the requirements of the proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2, including an implementation timetable and annual review of implementation status, should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading? For example, do you agree that a capital project is not required to be implemented by Requirement R4, Parts 4.2.2.1 and 4.2.2.2, even if the capital project is the only feasible action available to prevent the System from Cascading when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

3. Do you agree with the omission, as proposed in TPL-001-5 Requirement R4, Part 4.2, of a requirement similar to that of Requirement R2, Part 2.7, which states that the planned System shall continue to meet the performance requirements in Table 1 in subsequent Planning Assessments?

4. Do you agree with including Table 1 Footnote 13 a., "[a] single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, *e.g.*, sudden pressure relaying", and its limitation to only the specific single protective relay and not to other elements of the associated Protection System?

5. Do you agree with the inclusion of Table 1 Footnote 13 b. & c. stipulation, "which is not monitored or not reported", and that it conveys the expectation that the monitoring and reporting is sufficient to result in prompt remediation addressing the failure status of the associated equipment?

6. Do you agree with the inclusion of Table 1 Footnote 13 d., and that it, in conjunction with defined terms, identifies what constitutes all of the elements of, "A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices."?

7. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that modify which known outages shall be represented in System models from those "with a duration of at least six months" to those selected by the Planning Coordinator (PC)/Transmission Planner (TP) "in consultation with" their Reliability Coordinators (RCs).

8. Do you agree with omitting the Reliability Coordinator (RC) from the applicability of the TPL-001-5 standard given that Requirement R1, Part1.1.2 requires consultation between the TP/PC and the RC to determine which known outages to select for representation in System models?

9. FERC Order No. 786 Paragraphs 40-45 direct modification to address significant planned maintenance outages with durations less than 6 months in planning assessments. Are you aware of an existing standard/requirement, consistent with industry practice and applicability that requires review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in System models (TPL 001-4 Requirement R1 Part R1.1.2)?

10. Do you agree with the 36 month implementation period to address all Requirements except for Requirement R4, Part 4.2, and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.

11. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.2 and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.?

12. In looking at all proposed recommendations from the standard drafting team, are the proposed changes a cost effective approach which meets the FERC directives? (*see* *Cost Effectiveness Background Document*)

13. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

14. Do you have any other general recommendations/considerations for the drafting team?

1. Do you agree that an associated timetable for implementation of actions needed to prevent the System from Cascading (TPL-001-5 Requirement R4, Part 4.2.2.1) and an annual review of implementation status (TPL-001-5 Requirement R4, Part 4.2.2.2) should be required when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

Answer	No
Document Name	
Comment	
SCL does not agree with the implementation of corrective action plan and the requirement for an annual review of the implementation status when analysis concludes there is Cascading caused by extreme events. Implementing actions for extreme events can be costly, and may not produce much benefit because of the low frequency of these types of events happening.

Requirement 4.2.2 NERC requires listing of possible actions, which is ok. However, 4.2.2.1 requires a timetable for implementation. In the past, the decision to mitigate extreme events has been left to the discretion of the Planning Coordinator. The PC is best able to set their risk tolerance or do a cost/benefit analysis to determine whether the Corrective Action Plan should be implemented. If the PC has no plans to implement the corrective action plan then why does a timetable need to determined and followed up in subsequent assessments.

BPA does not agree with separating out extreme events in 2e-2h for mitigation, everything should be included in 4.2.1. BPA suggests removing any reference to implementation status and timetables. BPA suggests only including requirements for performing studies to assess the impact, analyzing the results and evaluating possible actions to reduce the likelihood or mitigate the consequences of extreme events.

BPA believes that it is not economically justifiable to require corrective action plans for low probability extreme events like these. Instead, BPA believes an effort to minimize the likelihood of cascading should be considered if studies indicate there is the potential for cascading on critical parts of the system.

AEP disagrees. These proposed subrequirements exceed the authorization of the SAR. They attempt to convert certain extreme category events involving failure of a non-redundant component of a protection system into quasi-planning events where cascading is to be prevented (though while other performance requirements on consequential load loss, exceeding facility ratings, voltage deviations, etc., are omitted). In addition, AEP questions the benefit of devising preventive actions and an associated timetable, and performing an annual review of implementation status for mitigating actions that are supposedly never to be “required.”

AZPS does not support the inclusion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2. It is AZPS's understanding that, based on previous stakeholder input, the SDT determined that a Corrective Action Program (CAP) requirement was not appropriate for these extreme contingencies. AZPS respectfully submits that, although the verbiage has been revised, the obligation on entities as a result of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 essentially amounts to a CAP requirement. In fact, AZPS reads the requirements of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 as providing an even more rigorous obligation than other CAP requirements. For example, in Requirement R2.8, the CAP requires 3 actions: (1) a list of deficiencies, (2) the actions necessary to address these, and (3) an annual review for continued validity and status. Parts 4.2.2, 4.2.2.1, and 4.2.2.2 require: (1) a list of deficiencies, (2) the actions necessary to address these, (3) a timetable for implementation, and (4) annual review for continued validity and status. Thus, in comparing requirements for a CAP and the requirements set forth in Parts 4.2.2, 4.2.2.1, and 4.2.2.2, it is clear that, despite stakeholder input, Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are still requiring a CAP even though the contingencies to be addressed are extreme, unlikely to occur, difficult and expensive to address, and unlikely to significantly improve reliability. Finally, AZPS respectfully suggests that it is not cost effective to attempt to resolve system efficiencies as a result of such extreme events. Such activities have a very low cost/benefit ratio, and will result in the unnecessary expenditure of resources by registered entities. For these reasons, AZPS cannot support the inclusion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 and, therefore, cannot support an associated timetable for implementation or annual review of implementations status. AZPS recommends the deletion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 from TPL-001-5.

If Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are not removed as requested above, AZPS submits the following suggested language:

4.2.2 If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e -2h the stability c and/or PC shall:

4.2.2.1 Document the list of System deficiencies and actions that could be taken to prevent the System from Cascading.
4.2.2.2 Review the list of System Deficiencies and potential actions to address such System deficiencies in subsequent annual Planning Assessments for continued validity

Comment	

JEA appreciates the effort of the SDT addressing the directives from the Commission on Order No. 786 as well as the recommendation from the SPCS and the SAMS from the assessment of protection system single points of failure in response to Order No. 754. The clarification of relay to components of a Protection System with the additional footnote to clarify P5 and extreme events – stability 2e-2h is a significant improvement to the proposed TPL-001-5. It addresses ALL the recommendations from SPCS and SAMS regarding single points of failure in protection systems in the report from Section 1600 Data Request following Order No. 754. This Order was issued directing NERC and Commission staff to initiate a process to identify any reliability issues for system performance following the loss of a single BES Element which appeared in the legacy TPL (version 0) standards. The conclusion from the report has rightfully and adequately addressed the Commission's concern. In general, the proposed TPL-001-5 removes the ambiguity from the legacy TPL standards for protection system failures.

However, the proposed new Requirement 4, Part 4.2.2, subparts 4.2.2.1 and 4.2.2.2 go beyond the recommendation from the Section 1600 Data Request report for Order No. 754. The issue of 'Cascading caused by the occurance of extreme events' is already addressed by part 4.2.1 that 'an evaluation of possible actions designated to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.' Besides, a Cascading caused by the extreme event due to protection system single points of failure (Table 1 Extreme Events – Stability 2e-2h) is no different than a Cascading due to any other extreme event (Table 1 Extreme Events – Stability 2a-2d, 2i-2j) - a Cascading is a Cascading; the end result is the same. And the Section 1600 Data Request report has very clearly put this in their conclusion in the second paragraph which is copied below verbatim:

"Additional emphasis in planning studies should be placed on assessment of three-phase faults involving protection system single points of failure. This concern (the study of protection system single points of failure) is appropriately addressed as an extreme event in TPL-001-4, Part 4.5. From TPL-001-4, Part 4.5: If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted."

The added clarification under Table 1 for Planning Event P5 and extreme event – stability 2e-2h along with footnote 13 sufficiently covers all the concerns that the Commission expressed in Order No. 754 as well as the conclusion and recommendation from the analysis for the same in the aforementioned report for the protection system single points of failure.

In addition, the conclusion of the above report did not recommend setting the bar "higher" for performance than it is for current TPL-001-4 for extreme events in TPL-001-4 Part 4.5 nor did the SAR authorize the SDT to do this. Any Cascading due to an extreme event is already addressed in the Commission approved TPL-001-4 in Requirement 4, Part 4.5 wherein an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) is warranted.

Suggestion: Part 4.2.2, subparts 4.2.2.1 and 4.2.2.2 of the Requirement 4 is not needed as the issue of Cascading due to the extreme events is already covered by Part 4.2.1. Delete "excluding extreme events 2e-2h in the stability column" from Part 4.2.1 and it will cover ALL the Cascading due to extreme events

Part 4.2.2 of TPL-001-5 implies a requirement to implement actions to prevent the System from Cascading caused by extreme events, a criterion beyond the basic design and planning criteria. This requirement essentially moves such events into the “Steady State & Stability Performance Planning Events” table and a consideration for R2, R3 and R4 for which any unacceptable performance will require actions to mitigate the risks/reliability impacts. This is contrary to the intent of listing the 2a to 2j events under the Extreme Event table. We objected to the previous draft TPL-001 revision because it called for a Corrective Action Plan (CAP) to avoid or mitigate such reliability impacts. Although this new draft standard removed a specific CAP requirement, it appears that this revised version continues to require implementation of actions to mitigate or avoid Cascading due to low probability	

extreme events, no matter the cost. We have no issue with requiring an evaluation of possible actions needed to prevent the System from Cascading, but we do object to a further requirement to implement an action or actions without considering cost and other factors.

WAPA believes there is risk with the proposed changes of the single point of failure (SPF) language that will not significantly improve reliability. There is likelihood this change may even reduce reliability by having the CAPs force entities to redirect its limited resources away from other important reliability needs to solve SPF identified issue. Further, implementation of the CAPs may likely cause significant mis-ops while system protection systems are being modified to eliminate SPFs thus reducing reliability and increase risk to the transmission system. We would also like to point out that there is no corresponding directive from FERC in the SAR.

Suggest that Part 4.2.2 and its sub Parts can be struck. If there is a corrective action plan required, as implied by 4.2.2.1, then this event should be listed in Table 1 P5 instead of the Extreme Event Table. Also, in 4.2.1, strike the phrase “excluding extreme events 2e – 2h in the stability column”. The strategy to manage extreme events should be the same for all categories of extreme events – and as such, the requirements in 4.2.1 (i.e., evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the events(s) shall be conducted) is sufficient.

No. Question 1 and the referenced standard language state that a CAP is required but Question 2 implies that implementation of the CAP is not required. The SDT should consider clarifying how implementation status will be reviewed when no implementation is actually required. This lack of clarity may lead to inconsistent interpretation by Registered Entities as well as Regional Entities on what constitutes compliance.

Although the drafting team made its rationale clear for including a requirement for entities to document an associated timetable and perform annual reviews for the extreme events 2e-2h that result in cascading, SCE advocates that this language confuses the intent and will create compliance ambiguity in the future. SCE proposes that the drafting team remove sub-requirement R4.2.1 and R4.2.2 (and the underlying R4.2.2.1 & R4.2.2.2) entirely. This change will significantly reduce the confusion for the intention to not obligate entities to actually implement actions identified, and it will keep the compliance obligation clear in the future. Entities should look into actions that may reduce exposure or impact for 2e-2h in the same manner as other extreme events. Requiring a timetable without an obligation to implement does not add value to system planning.

Answer	No
Document Name	
Comment	

CenterPoint Energy Houston Electric, LLC (“CenterPoint Energy”) disagrees with the wording in Requirement R4, Parts 4.2.2.1 and 4.2.2.2 related to implementation. The wording related to implementation could be interpreted as requiring the actual implementation of actions identified as being needed to prevent the System from Cascading. Additionally, the wording related to implementation may be inconsistent with other provisions in TPL-001-5. Requirement R3, Part 3.5 has a similar identification and listing requirement regarding extreme events in the steady state portion of the Planning Assessment. However, there is no wording related to implementation in Requirement R3, Part 3.5.CenterPoint Energy recommends wording for Parts 4.2.2.1 and 4.2.2.2 be similar to Requirement R3, Part 3.5 and that references to implementation be removed.

CenterPoint Energy recommends that Parts 4.2.2.1 and 4.2.2.2 be revised as follows:

4.2.2.1. List System deficiencies and the associated actions needed to prevent the System from Cascading.

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity.

Comment

We do not agree with adding Parts 4.2.2.1 and 4.2.2.2 as they imply requiring implementation of actions needed to prevent the System from Cascading caused by extreme events – a criterion beyond the basic design and planning criteria. Adding these two parts essentially moves them into the “Steady State & Stability Performance Planning Events” table and a consideration for R2, R3 and R4 for which any unacceptable performance will require actions to mitigate the risks/reliability impacts. This is contrary to the intent of listin g the 2a to 2j events under the Extreme Event table.

We strongly recommend the SDT to revert R4 to the currently approved version (TPL-001-4).

Additional Comment for consideration, related to Requirement #4 (related to clarification of the Standard):

Requirement 4.1 states that “Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1…..” Immediately after 4.1, sub-requirements 4.1.1 through 4.1.3 specify specific system/generator stability performance requirements which are not mentioned in Table 1. Our observation is that Table 1 includes steady state and stability related performance requirements. This apparent placement of performance requirements in more than one location within the Standard document is confusing. Recommendation for consideration is to move sub-requirements 4.1.1 through 4.1.3 to Table 1.

Comment

This overcomplicates the standard. The purpose of extreme event analysis is to understand the potential consequences of extreme events and to develop some ideas on how to address extreme events that result in cascading or instability. However, the current standard stops short of requiring corrective action plans, but defers to the PC/TP to make that determination based on the i) probability of occurrence, ii) level of impact, and iii) cost to mitigate or remedy. On the other hand, the purpose of planning contingencies (P1-P7) is to dictate minimum performance standards and require corrective action plans if performance does not meet the requirements of the standard. This clear distinction between planning contingencies and extreme event contingencies should be maintained for clarity and to avoid confusion. Therefore, to the extent it is desirable to modify the TPL standard to require corrective action plans for certain extreme events under certain situations, it would be better to move such events into the planning contingency category. That is, if it is desirable to require that corrective action plans be developed for three-phase faults with delayed clearing due to protection system failure if such events cause cascading or instability, then a P8 contingency should be created for this purpose, thus moving the three-phase fault with delay clearing out of the extreme event category and into the planning event category.   This maintains a clear distinction between extreme events and planning events.

We would agree if the Standard Drafting Team would make it clear whether an implementation of a Corrective Action Plan is mandated in the Standard for Requirement R4, Part 4.2.2. While we agree that all mandated Corrective Action Plans (NERC defined term) should have an associated timetable for implementation (and possibly annual review of its status), we do not agree with requiring a timetable for implementation actions and annual review of implementation status if the Corrective Action Plan is not mandated.

If the Standard Drafting Team intends for these actions to be implemented, we will recommend using "Corrective Action Plan", which is a NERC defined term and eliminates the ambiguity in the requirement.

GTC does not support the inclusion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2, for similar reasons to AZPS:

It is AZPS's understanding that, based on previous stakeholder input, the SDT determined that a Corrective Action Program (CAP) requirement was not appropriate for these extreme contingencies. AZPS respectfully submits that, although the verbiage has been revised, the obligation on entities as a result of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 essentially amounts to a CAP requirement. In fact, AZPS reads the requirements of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 as providing an even more rigorous obligation than other CAP requirements. For example, in Requirement R2.8, the CAP requires 3 actions: (1) a list of deficiencies, (2) the actions necessary to address these, and (3) an annual review for continued validity and status. Parts 4.2.2, 4.2.2.1, and 4.2.2.2 require: (1) a list of deficiencies, (2) the actions necessary to address these, (3) a timetable for implementation, and (4) annual review for continued validity and status. Thus, in comparing requirements for a CAP and the requirements set forth in Parts 4.2.2, 4.2.2.1, and 4.2.2.2, it is clear that, despite stakeholder input, Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are still requiring a CAP even though the contingencies to be addressed are extreme, unlikely to occur, difficult and expensive to address, and unlikely to significantly improve reliability. Finally, AZPS respectfully suggests that it is not cost effective to attempt to resolve system efficiencies as a result of such extreme events. Such activities have a very low cost/benefit ratio, and will result in the unnecessary expenditure of resources by registered entities. For these reasons, AZPS cannot support the inclusion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2 and, therefore, cannot support an associated timetable for implementation or annual review of implementations status

Answer	No
Document Name	

Comment

Duke Energy disagrees with the use of the term "implementation" in 4.2.2.1 and 4.2.2.2. Currently as written, a Planner is only required to conduct an evaluation of possible actions to reduce likelihood of Cascading resulting from extreme events. There is no further requirement for additional action other than what the evaluation must be comprised of. The use of the term "implementation" implies that an action other than the evaluation is required. The drafting team should consider adding additional language stating that implementation of said actions, are at the discretion of the Planner.

CHPD does not agree with implementing a corrective action plan or an annual review of implementation status for preventing Cascading for Extreme Events. Extreme Events have a low likelihood of occurring and to mitigate these types of events would be costly and not provide much benefit due to their low likelihood of happening. The reference to a timetable, without a requirement to actually implement, may additionally provide a source of confusion. As an example, if a project would be needed seven years into the future, would it be appropriate for the timetable to reflect this seven year deadline, or should it reflect the system changes required to meet the seven year deadline? As a second example, if based on this analysis, system changes are immediately required to prevent Cascading, what should this timeframe reflect?

The second point of confusion is the language referencing the word “action”. Action is an undefined term, and thus is subject to multiple potential interpretations. Is the reference to action to mean that manual operator action is acceptable, or does action refer to a capital project to enact system changes to prevent the Cascading? This is unclear based on NERC and industry dialogue on this point.

The current language in TPL-001-4 only references an evaluation of possible **actions** designed to reduce the likelihood **or** mitigate the consequences of the event, not to determine a system change to fully mitigate the Cascading. There are two changes in the new proposed standard – the first is that the Cascading MUST have a fully mitigated solution (whereas the previous version also allowed a reduction of the likelihood) and the previous standard’s wording of action seemed to indicate the use of operator action, whereas the new standard’s discussion of timetables and implementation status is more consistent with the definition of action associated with the required system changes under the Corrective Action Plans.

Comment

The extreme events 2e-2h involve three-phase faults with delayed clearing. Three-phase faults are considered uncommon and very unlikely. If this involved single-phase faults with delayed clearing, then Oncor could agree with an associate time table since they are more probabilistic and feasible in terms of a capital project. The probability of a 3 phase fault along with delayed clearing of the fault is extremely unlikely. Additionally, an occurrence of this magnitude will generally involve shedding load and isolating the rest of the fault from the system.

We believe that the proposed changes are confusing. It appears that the addition of part 4.2.2 requires a fix to prevent cascading for extreme events caused by non-redundant relaying components, while part 4.2.1 would continue to allow cascading for stuck breaker conditions. Why does part 4.2.2 require fixes for failure of non-redundant relaying components? Why isn't this requirement part of the PRC standards, but is instead proposed for standard TPL-001?

Extreme Events have a low likelihood of occurring and to mitigate these types of events would be costly and not provide much benefit due to their low likelihood of happening. The reference to a timetable, without a requirement to actually implement, may additionally provide a source of confusion. As an example, if a project would be needed seven years into the future, would it be appropriate for the timetable to reflect this seven year deadline, or should it reflect the system changes required to meet the seven year deadline? As a second example, if based on this analysis, system changes are immediately required to prevent Cascading, what should this timeframe reflect? The second point of confusion is the language referencing the word “action”. Action is an undefined term, and thus is subject to multiple potential interpretations. Is the reference to action to mean that manual operator action is acceptable, or does action refer to a capital project to enact system changes to prevent the Cascading? This is unclear based on NERC and industry dialogue on this point. The current language in TPL-001-4 only references an evaluation of possible **actions** designed to reduce the likelihood **or** mitigate the consequences of the event, not to determine a system change to fully mitigate the Cascading. There are two changes in the new proposed standard – the first is that the Cascading MUST have a fully mitigated solution (whereas the previous version also allowed a reduction of the likelihood) and the previous standard’s wording of action seemed to indicate the use of operator action, whereas the new standard’s discussion of timetables and implementation status is more consistent with the definition of action associated with the required system changes under the Corrective Action Plans.

To answer the question directly, the SRC does not believe it is appropriate to require the development of a timetable for implementation of a corrective action plan to address performance issues caused by extreme events. Additionally, an annual review of the implementation status should not be required for extreme events.

More importantly, the SRC does not agree with adding Part 4.2.1 or Part 4.2.2. The substance of Part 4.2.1 is already included in Part 4.5 of R4. The addition of Part 4.2.2, including Parts 4.2.2.1 and 4.2.2.2, is also inappropriate because these provisions could be read to require the TP and PC to prescribe actions to prevent the System from Cascading caused by extreme events – a criterion beyond the basic design and planning criteria. Adding these two parts essentially moves them into the "Steady State & Stability Performance Planning Events" table and a consideration for R2, R3 and R4 for which any unacceptable performance will require actions to mitigate the risks/reliability impacts. This is contrary to the intent of listing the 2a to 2j events under the Extreme Event table.

The addition of Parts 4.2.1 and 4.2.2 also raises a process question. Inadequacy in addressing Cascading caused by Extreme Events was not at all mentioned in Orders 754 or Order 786, nor was it presented in the final SAR for this project. Such addition appears to be a self-directed initiative that goes beyond the scope of the project, which may be regarded as a deviation from established standard development processes. We urge the SDT to revert R4, Part 4.2, to the currently approved version (TPL-001-4).

Note: ISO-NE does not support this comment.

2. Do you agree that the requirements of the proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2, including an implementation timetable and annual review of implementation status, should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading? For example, do you agree that a capital project is not required to be implemented by Requirement R4, Parts 4.2.2.1 and 4.2.2.2, even if the capital project is the only feasible action available to prevent the System from Cascading when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

Comment	
TEP agrees that Requiement R4, Parts 4.2.2.1 and 4.2.2.2 should not mandate actual implementation of actions identified to prevent the System from Cascading. However, the language fail;s to get this point across. Requiring identification of actions to avoid a response along with a timeline to implementthe actions to mitigate the issue implies that these actions must be taken. R4 Part 4.2.2.2 further implies that an entity will be making progress to implement the corrective actions as it reviews the status of the mitigation each year. We agree that mitigation for an extreme event should not be required.

Comment	

A corrective action plan should not be required for an extreme event. Corrective action plans, however, should be required for planning events described in 2e through 2h. While these events are currently included in the extreme events section of Table 1, and since corrective action plans should only be required for planning events, the events described in 2e through 2h should be moved to the planning events section of Table 1 while keeping the criteria to maintain system stability and to avoid cascading or uncontrolled islanding. The Table 1 steady state and stability performance requirements (such as equipment loading, voltage and stability) shall not apply.

ISO-NE does not think that the requirements as written mandate a corrective action plan.

The term “Planning Assessment” is defined in the NERC Glossary as a “documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies.” We believe these studies should not be used as a tracking mechanism for Corrective Action Plans, including for those System deficiencies that would require transmission and generation infrastructure upgrades. We propose the removal of references to implementation and timetables and instead focus these requirements on the identification of System deficiencies and associated preventive actions.

We understand that Parts 4.2.2.1 and 4.2.2.2 require the implementation of corrective action plans to mitigate Cascading caused by extreme events 2e-2h, when analysis concludes a mitigation plan is needed, even if a capital project is the only feasible action available. Corrective action plans should be implemented to prevent Cascading; however, this should be limited to protection system projects. The Requirment (Parts 4.2.2.1 and 4.2.2.2), as written, calls for (1) studies to be performed; (2) evaluation of actions (i.e. solution) that would reduce or mitigate (i.e. solve) the identified deficiency; (3) timetable for implementation of the solutions; (4) annual review; and (5) listing of the implementation status. Therefore, the Requirment (Parts 4.2.2.1 and 4.2.2.2), as written, mandates actual implementation of actions identified as needed to prevent the System from Cascading. Actions to mitigate protection system single point of failure do not usually incur significant cost. Mitigating single points of failure is the direction from FERC order 754. Changes to this Standard was deemed to be the most effective means to accomplish this objective. If corrective actions (capital projects) are not required by this standard, then the FERC objectives may not be achieved which could lead to additional large scale system events or disturbances and additional FERC orders.

The requirements to have an implementation timetable and annual review, particularly of the "implementation status" suggests that 4.2.2 is mandating a Corrective Action Plan. If this is not the intent of 4.2.2.1 and 4.2.2.2, it must be clarified and explitcity indicated that implementation of a Corrective Action Plan itself (capital project or otherwise) is not required.

There appears to be very little difference between 4.2.1 and 4.2.2 other than making a list and establishing an implementation timetable that would be meaningless if there is no intent to implement the solution. The current TPL-001-4 wording is sufficient unless there is a desire to require development and implementation of a Corrective Action Plan for certain events and circumstances, in which case, as previously suggested, the contingency should be moved from the extreme event category to a planning contingency category. Otherwise the wording in the current standard regarding extreme events that are found to result in cascading and/or instability should not be modified.

CenterPoint Energy agrees that the requirements of the proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2 should not and do not mandate actual implementation of actions identified in the analysis as being needed to prevent the System from Cascading. However, CenterPoint Energy disagrees with the wording in Requirement R4, Parts 4.2.2.1 and 4.2.2.2 related to implementation. As discussed above, CenterPoint Energy recommends wording for Parts 4.2.2.1 and 4.2.2.2 be similar to Requirement R3, Part 3.5 related to extreme events for the steady state portion of the Planning Assessment.

CenterPoint Energy recommends that Parts 4.2.2.1 and 4.2.2.2 be revised as follows:

4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading.

4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity.

We agree that Parts 4.2.2.1 and 4.2.2.2 should not mandate actual implementation but disagree that the language for 4.2.2.1 adequately conveys this. Although the drafting team made its rationale clear for the additional proposed actions for the extreme events 2e-2h, SCE advocates that this language confuses the intent and will create compliance ambiguity in the future. SCE proposes that the drafting team remove sub-requirement R4.2.1 and R4.2.2 (and the underlying R4.2.2.1 & R4.2.2.2) entirely. This change will significantly reduce the confusion for the intention to not obligate entities to actually implement actions identified, and it will keep the compliance obligation clear in the future. Entities should look into actions that may reduce exposure or impact for 2e-2h in the same manner as other extreme events.

The words utilized in this question seem to imply that a Corrective Action Plan may not be required. However, the use of the phrases "associated timetable for implementation" and "implementation status" makes the intent misleading. It is unclear how this differs from Requirement 2.7 which states "Corrective Action Plan(s) addressing how the performance requirements will be met." Suggest that Part 4.2.2 and its sub Parts can be struck. If there is a corrective action plan required, as implied by 4.2.2.1, then this event should be listed in Table 1 P5 instead of the Extreme Event Table. Also, in 4.2.1, strike the phrase "excluding extreme events 2e – 2h in the stability column".

Comment

No, AZPS does not, based on its review of the language, agree that the Parts 4.2.2, 4.2.2.1, and 4.2.2.2 “should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading.” In fact, its comparison of the language to the language of those requirements associated with a mandatory CAP indicates that the language and obligations under Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are actually more robust and stringent. This comparison is provided above in Question 1. For these reasons, AZPS does not agree with the inclusion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2. AZPS submits that these requirements together amount to an actual implementation requirement, and that the language is consistent with a required/ mandatory CAP. Irrespective to whether or not a Transmission Planner believes a capital project is required to be implemented by Parts 4.2.2.1 and 4.2.2.2, the compliance will be determined by the language in the standard. If the language in Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are essentially the same as that for a CAP, the requirement is essentially equivalent to CAP.

If Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are not removed as requested above, to clarify the intent stated in this question, AZPS recommends the following revisions to the proposed language for Parts 4.2.2, 4.2.2.1, and 4.2.2.2:

4.2.2 If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e -2h

4.2.2.1 Document the list of System deficiencies and actions that could be taken to prevent the System from Cascading.

4.2.2.2 Review the list of System Deficiencies and potential actions to address such System deficiencies in subsequent annual Planning Assessments for continued validity

Comment

The language of these proposed subrequirements does not suggest that actual implementation is optional. The components of a Corrective Action Plan as defined in the NERC Glossary are clearly required by the proposed 4.2.2.1. 4.2.2.2 contains an expectation that the actions needed to prevent the cascading would be implemented at some point. Again, we question the point of devising preventive actions and an associated timetable, and performing an annual review of implementation status for mitigating actions that are supposedly never to be "required."

In addition, AEP does not agree that Correction Action Plans would be justified or necessary in every case. Considerations such as the nature and/or extent of any potential cascading should be a factor in determining whether or not a CAP is necessary, but as currently written, the obligation does not allow such engineering judgment. If mitigation is truly not required, then the language of R4.5 in TPL-001-4 is all that should be necessary.

Once again, as stated in our response to Question 1, AEP believes that pursuing Corrective Action Plans as part of R4, Part 4.6 goes beyond the scope of the current SAR.

Please note that AEP has chosen to vote Negative on TPL-001-5, in large part due to our objections as provided in our response to Questions #1 and #2.

The Requirment (Parts 4.2.2.1 and 4.2.2.2), as written, calls for (1) studies to be performed; (2) evaluation of actions (i.e. solution) that would reduce or mitigate (i.e. solve) the identified deficiency; (3) timetable for implementation of the solutions; (4) annual review; and (5) listing of the implementation

status. Therefore, the Requirment (Parts 4.2.2.1 and 4.2.2.2), as written, mandates actual implementation of actions identified as needed to prevent the System from Cascading.

BPA believes that requiring an implementation plan and timetable is similar to a corrective action plan and is being mandated. Until the studies are done, it can not be determined if any capital projects were included. In general, the utility will determine whether or not to address an issue based on risks and consequences of the event.

Requirement parts 4.2.2.1 and 4.2.2.2 require Responsible Entities to create associated actions and a timetable for implementation. Compliance enforcement staff could interpret the requirement such that a documented action is required to be implemented.

SRP agrees TPL-001-5 should not mandate actual implementation of a Corrective Action Plan. However, the current language of 4.2.2.2. leaves too much of a gray area that is open for interpretation as mandating actual implementation. SRP recommends removing 4.2.2.2. altogether. The impacts of extreme events 2e-2h in the stability column, and the actions required to prevent the System from cascading are addressed by 4.2.2. and the first part of 4.2.2.1. in every annual Planning Assessment. Requiring a review "for continued validity" is redundant, and requiring a timetable for implementation or a review of implementation status is unnecessary for a NERC Reliability Standard.

MH believes the language in 4.2.2.1 and 4.2.2.2, as written, mandates construction to prevent Cascading for extreme events. The wording of this question is confusing "... should not and do not mandate ...". If the first sentence is intended to breakup as follows:

Do you agree that …….. should not mandate ……? Answer - Yes

Do you agree that……… do not mandate …………..? Answer - No

The way it reads seems to imply an implementation of actions is required and that action could result in a capital project. If the only feasible means to prevent a cascading event is a capital project then this seems to be a meaningless exercise if there is no requirement to implement it. Permitting the implementation of capital projects to be optional when it is the only feasible solution subjects the utility to the possibility that the state commissions might view the capital project (expenditure) as not necessary for reliability given that the justification is based on an extreme event(s).

In addition to our comments under Q1, we believe that analyzing system performance when subject to "Extreme Events" is meant to provide a sense of where instability and/or Cascading could occur for the PC and/or TP to assess what actions could be developed to mitigate or reduce the potential impact. Such actions generally involve positioning the BES, adjusting outage plans, implementing operations strategies, developing a safe posture and preparing for resiliency plans, but not any capital investment projects. Note that this does not preclude the responsible entity from implementing any of these actions in its sole discretion, but it should not be mandated. Capital projects to address operational circumstances should not be mandated in a TPL standard. Further, requiring capital projects would exceed the scope of FERC Order 754 and 786 as well as the SAR. **Note: ISO-NE does not support this comment.**

Texas RE agrees that the current language does not mandate actual implementation. However, Texas RE would support requirements mandating implementation of the actions determined by the PC and TP to reduce the likelihood of Cascading consistent with regional planning processes.

Additionally, Texas RE would support the development of a Corrective Action Plan that included a capitol project designed to mitigate Cascading if that were the only option. Generally capital projects endure scrutiny by the planning processes in the Texas RE region.

The planned system should always meet the performance requirements in Table 1 in any Planning Assessment that is performed. To the extent a Corrective Action Plan is developed for issues identified in one Planning Assessment and the issues go away in subsequent Planning Assessments due to changes in load forecasts or other drives of the original issue, elimination or modification of the Corrective Action Plan in the subsequent Planning Assessment should certainly be allowed, but the language above that states "the planned System shall continue to meet the performance requirements in Table 1 in subsequent Planning Assessments" seems unnecessary since the Table 1 requirements apply to all Planning Assessments.

As mentioned in our response to Q2, our interpretation of Part 4.2.2 is that it requires the implementation of corrective action plans –including capital projects– when analysis concludes there is Cascading. We support the implementation of corrective action plans.

If the drafting team considers that this is not the intent of the revision, and the implementation of capital projects IS NOT required, we propose that Part 4.2.2 be revised to make this clear.

If a system risk or vulnerability has been identified as a result of conducting a mandatory reliability assessment, Corrective Action Plan(s) must be developed which maintains system performance. Customers and regulators will not accept that a system deficiency was identified but not mitigated by a Transmission Planner when such an event occurs. If maintaining system performance following an event is not required, then performing an assessment of that event should not be required.

While we agree that there should be an omission, the use of the phrases “associated timetable for implementation” and “implementation status” in R4.2 gives the perception that capital projects would be required. It is unclear how this differs from Requirement 2.7 which states “Corrective Action Plan(s) addressing how the performance requirements will be met.” Suggest that Part 4.2.2 and its sub Parts can be struck. If there is a corrective action plan required, as implied by 4.2.2.1, then this event should be listed in Table 1 P5 instead of the Extreme Event Table. Also, in 4.2.1, strike the phrase “excluding extreme events 2e – 2h in the stability column”.

To confirm, in summary R4.2 for extreme events has been re-drafted in R4.2.1. to exclude the new expanded definition of protection system failure events from the evaluation covered in R4.2.2. which specifically applies additional requirement to the new protection system failure events. Based on this interpretation, this is an acceptable omission for those non-protection system failure events. However, CHPD feels Corrective Action Plans should not be required to mitigate all Extreme Events (including protection system failure) because it would be costly and have little benefit as Extreme Events have a low likelihood of happening. Thus, these Extreme Events are studied for system awareness and determining the constraints of the system.

Part 2.7 is referring to the planning events Table 1 which has performance requirements for maintaining a normal system. Part 4.2 is referring to the extreme events, which does not have performance requirements in Table 1. A similar requirement is not needed because Part 4.2 says to perform studies to assess the impact of extreme events and conduct an evaluation of possible actions that could reduce the likelihood, mitigate, or prevent Cascading that occurs due to an extreme event in the list.

4. Do you agree with including Table 1 Footnote 13 a., "[a] single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, *e.g*., sudden pressure relaying", and its limitation to only the specific single protective relay and not to other elements of the associated Protection System?

Shannon Mickens - Southwest Power Pool, Inc. (RTO) - 2 - SPP RE, Group Name SPP Standards Review Group	
Answer	No
Document Name	
Comment	
The SPP Standards Review Group recommends that the drafting team provide more clarity in reference to the example in Footnote 13 (a) to refer to alternate performance to achieve electrical clearance rather than the relay to electrical quantities in which it may cause confusing on how it's interpreted.

Answer	No
Document Name	
Comment	
ISO-NE suggests revising footnote 13-1 to read as follows: 1. A single protective relay that is relied on for Normal Clearing times, without an alternative that provides comparable Normal Clearing times. A protection system may rely on a single protective relay that does not respond to electrical quantities such as a sudden pressure relay. Therefore, having the footnote refer to only relays that respond to electrical quantities may allow the failure of other critical relays to be ignored.

We believe the SDT should specify the actions taken by a single protective relay instead of identifying individual Protection System components for this standard. The reference to “an alternative that provides comparable Normal Clearing times” is confusing when associated with sudden pressure relays and included as a condition for non-redundant components of a Protection System.

Please clarify what constitutes an "alternative" relay. Is an "alternative" relay only referring to a relay that does not respond to electrical quantities? Further, what if alternative relay does not provide the same clearing time as primary relay (e.g., the alternate relay is an impedance relay with longer Zone 2 timer, or alternative relay is overcurrent relay, while primary relay is impedance relay). Is the alternative relay then considered as 'redundant', and therefore footnote 13 does not apply? We do not believe it is fully clear of what constitutes "comparable" in the context of comparable Normal Clearing times in Table 1 Footnote 13 Part 1. We further do not believe that it is fully clear what is required for a relay to be "monitored." Is it required that alarms are centrally monitored (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated)? Cf. 'Single Points of Failure TPL-001 Technical Rationale' document. Suggest adding parenthesis to clarify that sudden pressure relays are excluded. "[a] single protective relay which responds to electrical quantities (without an alternative that provides comparable Normal Clearing times, e.g., sudden pressure relaying)". As it is written currently, "sudden pressure relaying" would seem to respond to electrical quantities.

We agree with the attempt to clarify Table 1 Footnote 13 a. However, it is not clearly understood what is meant by the second part of the proposed statement "without an alternative that provides comparable Normal Clearing times, e.g., sudden pressure relaying". For example, does this mean that if an alternative that provides comparable Normal Clearing times exists, then the single protective relay that responds to electrical quantities is not considered "non-redundant" (and therefore would not be considered a non-redundant component of a Protection System)?? Recommendation is to re-word the sentence to make it absolutely clear.

The item label in TPL-001-5 is Footnote 13 1, not Footnote 13 a. We agree with having a single protective relay item in Footnote 13 and acknowledge that contemporary protective relay units normally perform multiple fault protection functions. However, we suggest removing the ", e.g. sudden pressure relaying" text for two reasons. First, sudden pressure relaying does not provide full redundancy of a transformer protection relay unit's functionality, but the present wording gives the impression that sudden pressure relaying will always provide full transformer protection relay redundancy. Second, the sudden pressure relay wording is somewhat confusing and can appear to identify sudden pressure relays as a type of protective relays to be evaluated.

Note: Equipment protection should not be confused with the TPL-001-5 reliability objective of providing adequate transmission capability to meet TPL-001-5 criteria avoiding instability, uncontrolled separation, and cascading. Sudden Pressure relays may be used as an additional protection to avoid equipment damage by removing a transformer quickly under specific conditions versus normal transformer differential protection.

NVE agrees with the intent of Footnote 13a, but would like to see clarification with the wording especially on terms (i.e. “comparable”). Perhaps, a defined term should be created similar to the WECC regional definition of ‘Functionally Equivalent Protection System’. Footnote 13a, could then be re-written to “[a] single protective relay without a Functionally Equivalent Protection System.” This would then cover multiple cases including the example provided in the Technical Rationale between the differential relay and sudden pressure relay.

Sean Bodkin - Dominion - Dominion Resources, Inc. - 6, Group Name Dominion

Answer	No
Document Name	

Comment

Dominion Energy agrees that other relay types such as sudden pressure relays can respond just as quickly to fault conditions and should be counted as a redundant component. Dominion Energy does not understand the rationale for limiting this to just the single protective relay and not other protective elements. For example, would it not be possible that the sudden pressure relay uses a separate trip path that would create the redundancy necessary? Should that not count towards the redundancy?

Comment

A sudden pressure relay doesn’t respond to electrical quantities. It is not even a component of a “Protection System,” which is the premise of the lead sentence of Footnote 13: “For purposes of this standard, non-redundant components of a *Protection System* to consider are as follows:” The drafting team may be confused because sudden pressure relays are included in PRC-005-6 – Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance. But as its title indicates, “Automatic Reclosing” and “Sudden Pressure Relays” are distinct from “Protection System.”

Footnote 13 should indicate that single protective relay applies to a relay unit and not a relay element. Multiple relay elements within a single relay unit (e.g., multiple elements in a common digital relay, etc.) are not redundant since a common failure (e.g., power supply) could impact all relay elements within the relay unit.

Armin Klusman - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	Yes
Document Name	
Comment	

CenterPoint Energy agrees with including Table 1 Footnote 13 a., “[a] single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, *e.g.*, sudden pressure relaying.” Presently, only Sudden Pressure Relaying meets this wording based on a NERC System Protection and Control Subcommittee report (Sudden Pressure Relays and Other Devices that Respond to Non-Electrical Quantities - SPCS Input for Standard Development in Response to FERC Order No. 758, December 2013) and the approved NERC Standard PRC-005 Protection System, Automatic Reclosing, and Sudden Pressure Relaying Maintenance. The proposed wording by the SDT for Table 1

Footnote 13 allows other types of relays that do not respond to electrical quantities to be added in the future, when approved, eliminating the need to revise this requirement in TPL-001-5.

This question is not worded very clearly. We believe the question is asking whether we agree that the language added should only apply to 13a and not to 13 b, c, or d (which we agree with). However, as written, it is very confusing since the quotes include the term "single protective relay" and then we are asked if we agree to "its limitation to only the specific single protective relay".

The Technical Rationale provides an example of fault in a transformer and the use of a sudden pressure relay. However, this is of no practical value since the Transmission Planner still has to account for the fault outside of the transformer tank and the sudden pressure relay will not protect against that. There is no benefit of adding this language related to an alternative device.

If the scope was broadened to include other elements associated with the Protection System (like PTs, CTs, Comm gear, etc.) the contingency list would be overbearing and would not add any benefit to the analysis. Failure of these other elements would produce redundant results to protection system failure events which are already evaluated. CHPD finds this clarification helpful in explaining the expectation of the applicable requirement, but would also note that this definition of non-redundant components is different than the other NERC definitions of non-redundant components addressed in the 2009 NERC document “Protection System

Reliability – Redundancy of Protection," as well as some of the redundancy methods and requirements described in PRC-012-2 (for RAS systems), which is subject to future enforcement. These multiple NERC definitions of acceptable types of redundancy will likely cause confusion in industry.

Texas RE agrees with including protective relays in Footnote 13. As stated in its comments for the Standard Authorization Request (SAR), Texas RE noticed the proposed language for Footnote 13 does not match the NERC Glossary term of Protection System. The NERC Glossary definition states: “Protective relays which respond to electrical quantities” while Footnote 13 states “a single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g. sudden pressure relaying.” Texas RE recommends Footnote 13 align with the NERC Glossary to avoid confusion. Texas RE noticed Footnote 13 is listed in number format, not letters as questions 4, 5, and 6 indicate on this form.

If the scope was broadened to include other elements associated with the Protection System (like PTs, CTs, Comm gear, etc.) the contingency list would be overbearing and would not add any benefit to the analysis. Failure of these other elements would produce redundant results to protection system failure events which are already evaluated.

CHPD finds this clarification helpful in explaining the expectation of the applicable requirement, but would also note that this definition of non-redundant components is different than the other NERC definitions of non-redundant components addressed in the 2009 NERC document “Protection System Reliability – Redundancy of Protection,” as well as some of the redundancy methods and requirements described in PRC-012-2 (for RAS systems), which is subject to future enforcement. These multiple NERC definitions of acceptable types of redundancy will likely cause confusion in industry.

5. Do you agree with the inclusion of Table 1 Footnote 13 b. & c. stipulation, “which is not monitored or not reported”, and that it conveys the expectation that the monitoring and reporting is sufficient to result in prompt remediation addressing the failure status of the associated equipment?	
Mike Smith - Manitoba Hydro - 1	
Answer	No
Document Name	
Comment	
It is questionable how monitoring will help in the case of a single protection channel. If the monitoring indicated the channel was not available, would the transmission line be taken out of service? The problem is how reliable is the monitoring? The concern is the case when a fault occurs and the single communication system fails. If monitoring is secure and the system can handle an outage of the line to fix the communication system, it’s not a bad strategy to save cost.

Thomas Foltz - AEP - 5	
Answer	No
Document Name	
Comment	
AEP seeks clarity regarding the intent of the use of the terms “not monitored or not reported.” Is the intent of the SDT to align with alarming and monitoring functions outlined in PRC standards? Furthermore, it appears that if the components are either monitored OR reported (but not both) it would meet the intent of Footnotes 13b & c. As proposed in the proposed draft, an entity would only have to monitor but not have to report or annunciate for the abnormal conditions specified in Footnote 13a & 13b.

The item labels in TPL-001-5 are Footnote 13 2. & 13 3., not Footnote 13 b. & 13 c. We agree with having a single communications system item in Footnote 13. However, we suggest limiting applicable communications systems to those that were installed specifically to assure crucial Normal Clearing times. We agree with having a single DC supply associated with protective functions item in Footnote 13 and with exempting those single DC supplies that are monitored or report both open voltage and open circuit.

Jeffrey Watkins - Jeffrey Watkins On Behalf of: Kevin Salsbury, Berkshire Hathaway - NV Energy, 5; - Jeffrey Watkins

Answer	No
Document Name	

Comment

NVE would like to see more clarification with monitoring and reporting. The frequency and definition of the monitoring should be more specific. If an entity inspects a substation once a year, and considers that as monitoring the DC supply, that does not seem like an effective method for excluding a study of a non-redundant DC supply since the DC supply could then fail within the year period and wouldn't be known until the next inspections. Adding some wording that defines monitoring and reporting would eliminate any confusion. An example would be "alarming for failure within 24 hours of detection to a location where corrective action can be intitiated."

The terms “monitored” and “reported” need to be fleshed out more. For example, communication circuits can be monitored continuously, daily, weekly, or monthly. What level of monitoring qualifies? The term “reported” could be to an annunciator panel in a station that may be monthly reviewed or it could be to an operations center that is staffed 24/7. See PRC-005-6 Tables 1-2, 1-4, and 2 for examples of how these terms can be used more clearly. We suggest the SDT consider defining these terms as they are used in multiple standards now.

Using the term "reported" is confusing given the expectation that remediation of a failure status is "prompt". Other standards have already established terms for what is considered "monitored", such as PRC-005. Can we not rely on these established concepts?

With regard to communication-assisted protection system where a communication signal is required for tripping and normal clearing, this should be considered a single-point-of-failure regardless of whether or not it is monitored. So the answer is NO for Footnote 13.b. With regard to DC supply, since there is some redundancy between the battery and the battery charger, the answer is YES for Footnote 13.c, but there should be additional language that requires separate protection (fuse or circuit breaker) for the battery and the battery charger so once can operate without the other.

The PC or TP will be able to determine if communication systems and DC supplies are monitored but it will not know if they are reported. It is presumed that if they are monitored they are reported.	

Please consider eliminating the requirement to monitor and report “open circuit” conditions, since such conditions would be tested and maintained per NERC Reliability Standard PRC-005 ‘Protection System, Automatic Reclosing, and Sudden Pressure Relaying’. We believe that preventive maintenance per PRC-005 provides reasonable and sufficient assurance for detection and handling “open circuit” conditions.

The above question misidentifies items 2 and 3 of footnote 13 as letters “b” and “c.” We concur that the meaning of “not monitored or reported” regarding a single communications system or dc supply associated with protective functions does convey an expectation that operating personnel who are monitoring such equipment will initiate field remediation activities to mitigate a failure. However, the proposed footnote should limit the inclusion of these Protection System components to only critical sites and at the discretion of the PC or TP.

The SPCS concluded that analysis of communications systems with regard to single points of failure did not pose enough of a risk to warrant addition in footnote 13. This assessment was based on SPCS efforts over the years studying blackouts/significant events and their causes. Communication system failures were not a causal factor in the significant events studied by the SPCS. Failures of relays and auxiliary relays have been causal in significant events. We recommend removing communication systems from footnote 13 in the revised standard.

A more explicit definition of the control circuitry is needed. Does this include the cables, auxiliary relays, cable routing? The cables are routed in a controlled environment, therefore have less exposure. Lockout relays and trip coils are monitored for integrity of the trip coil path. Does this eliminate the need for separate control circuitry? Our interpretation is that a shared controlled circuit as defined would need to meet clearing time concerns as defined, each relay function requiring a separate control circuit.

Non-redundant components should not consider a single trip coil. Consaidering the trip coil goes beyond non-redundancy of the protection system, in essence the SDT is considering non-redundancy of circuit breakers or other interrupting devices. Please clarify what constitutes “control circuitry.” Please consider adding text from (or referring to) relevant technical rationale document(s), which describes the applicable portions of a “Protection System” as defined in the NERC Glossary of Terms.

We feel that it is possible that the revised Table 1 Footnote 13 d helps to identify what constitutes all of the elements of, “A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices.” However, considering the complexities of Footnote 13 d, sample, or representative protection system diagrams and circuitry that would constitute examples of non-redundant components of a Protection System would be helpful. Such diagram(s) are recommended, and would provide clarity in a similar fashion as the diagrams provided in the NERC BES Reference Document.

Monitoring trip coils will ensure that the circuit breaker will trip but as the drafting team points out, it will not ensure that all the electromechanical lockouts (#86) nor the tripping auxiliary relays (#94) will work properly. While it is correct that PRC-005 monitoring does not include electromechanical lockouts (#86) nor tripping auxiliary relays (#94), these components are tested independently as prescribed by PRC-005 to ensure they are working properly. If the transmission system should be designed to be resilient against electromechanical lockout failure or tripping auxiliary relay failure, it doesn't make sense to include testing requirements under PRC-005. Conversely, if we require the industry to test these components, it is extraneous to build the system to be resilient to failure of these components. The number of low-probability events that must simultaneously occur already stretches the bounds of what is reasonable to justify grid expansion (through redundancy or other projects). PRC-005 is already a mitigating activity to the probability of those events and trip coils that are monitored in real-time should be excluded from footnote 13 d.

The item label in TPL-001-5 is Footnote 13 4, not Footnote 13 d. We agree with having a single control circuitry item in Footnote 13. However, we suggest replacing reference to interrupting device trip coils with reference to auxiliary relays in the interrupting device control circuity. The failure of an auxiliary relay in an interrupting device trip circuit may result in the tripping of more elements than P4 events (fault plus stuck breaker). The simulation of a single interrupting device trip coil failure is expected to be the same as the simulation of a P4 (fault plus stuck breaker) category event.

The wording in this bullet is somewhat confusing. We recognize that a, b, c, and d in footnote 13 are an attempt to adapt the definition of Protection System, and the original text was "DC control circuitry associated with protective functions through the trip coils…". However, now that we have added "single" to the phrase – it is a single control circuit, or a single portion of a control circuit, to which we are referring? "Single control circuitry" appears to be a mix of singular and plural contexts, or even a mix of a context which is specific to a quantity with one which is inherently both singular and multi-faceted. The SPCS report, page 11, recommended using "(3) DC control circuitry associated with protective functions…" which we would take to mean "the intended outcome of the DC control circuit associated with a protective function, or associated with multiple protection functions, does not come to pass". In this way, it can be adapted to any circuit design by the engineer, applying sound engineering judgment, to determine whether there are any portions of that circuit which may result in significant "failure to perform" outcome. With the term "single" the sentence could be read to mean "the entirety of the control circuit, including every component" since "circuitry" is both singular and multi-faceted in its use. Also, in other standards, DC control circuitry is inclusive of certain auxiliary relays, but this is not clear in the statements added. We suggest either sticking with the original language recommended from the SPCS or using one of the adaptations we've written above to clarify that the engineer should review the components (segments, sub-sections, branch connections – select as you see fit) of each control circuit to look for portions of any circuit associated with a protective relay whose failure could result in more circuit performance failures than just that of one protective relay.

Comment

We agree with having a single control circuitry item in Footnote 13. However, we suggest replacing reference to interrupting device trip coils with reference to auxiliary relays in the interrupting device control circuity. The failure of an auxiliary relay in an interrupting device trip circuit may result in the tripping of more elements than P4 events (fault plus stuck breaker). The simulation of a single interrupting device trip coil failure is expected to be the same as the simulation of a P4 (fault plus stuck breaker) category event.

Comment

The scenario described in Footnote 13d is the exact scenario studied under Category P4. Failure of a single trip coil in a breaker would result in the exact same scenario as a stuck breaker during a fault. Studying a P4 event and a P5 event for Footnote 13d would result in the same contingency. NVE feels that Footnote 13d should be removed and Footnote 10 be modified to include scenarios such as single trip coils.

Comment	
As similarly requested in previous comment periods, AEP once again requests additional clarification of footnote 13.4 regarding the phrase “Including the trip coil(s) of the circuit breakers or other interrupting devices.” For example, in the data request associated with FERC Order 754 (Single Point of Failure on Protection Systems), local breaker failure protection was allowed to be modeled in cases of non-redundant trip coils. In addition, the NERC System Protection and Control Task Force Technical Paper ‘Protection System Reliability Redundancy of Protection System Elements’, provides the following clarification: “A properly designed breaker failure scheme meeting all the requirements of the TPL standards and the proposed Protection System redundancy requirements could be used to overcome a breaker with only one trip coil or two trip coils operated in parallel.” As a result, AEP requests the previous clarification text be added to footnote 13.4 : **“A properly designed breaker failure scheme meeting all the requirements of the TPL standards and the proposed Protection System redundancy requirements could be used to overcome a breaker with only one trip coil or two trip coils operated in parallel.”** Please note that AEP has chosen to vote Negative on TPL-001-5, in part driven by our concerns as provided in our response to Question #6.

BPA believes that regarding a non redundant single trip coil resulting in a breaker not acting as appropriate, there are other contingency categories that require us to plan for breaker failure such as Category P2 and P4. BPA believes this should not be noted in the footnote and “13d” should be removed.

With regard to whether or not Footnote 13.d should be included, the answer is Yes, we believe DC control circuitry should be included as a potential single point of failure. However, we believe the language should be expanded to explicitly include auxiliary relays and lockout relays as part of the DC control circuitry for clarity. Furthermore, the DC control circuitry should be further characterized as “tripping DC control circuitry required for Normal Clearing” so that it is clear that single point of failure does not apply to DC closing circuitry or other DC circuitry no required for tripping. In addition, the footnote should limit the tripping DC control circuitry required for Normal Clearing to only that part of the circuitry that would prevent both tripping and initiation of breaker failure. To the extent a single point of failure prevents tripping but does not prevent breaker failure initiation, this contingency would be addressed by a P4 stuck breaker contingency. Finally, should there be a single point of failure in the DC control circuitry that prevents tripping of two circuit breakers but allows for breaker failure initiation on the two circuit breakers, this contingency is worse than a P4 contingency since it represents two stuck breakers, and such an event should be simulated as an independent type of single failure mode under the P5 contingency (while more adverse than a single stuck breaker contingency, it may less adverse than a complete system protection failure which could result in longer clearing delays and additional facilities tripped).

7. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that modify which known outages shall be represented in System models from those “with a duration of at least six months” to those selected by the Planning Coordinator (PC)/Transmission Planner (TP) “in consultation with” their Reliability Coordinators (RCs).

Ginette Lacasse - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body

Answer	No
Document Name	

Comment

The PCs and TPs are responsible for complying to the TPL-001-4 standard. RCs are under no obligation to comply with same and have no reason to have input on planning horizon outages (more than 1 year out) that are outside the operations planning horizon (less than 1 year out). No additional entities should be added to the applicability of this standard, including the RC, who is focused on the operations of the system. A gap in communication between PCs/TPs and RCs may put the PCs/TPs in a position where compliance for this standard are not met. In addition:

- The RC has no reason to have detailed information on outages in the planning horizon beyond what is in COS
- Having to respond to every entity within the reliability coordinator area could present an unreasonable burden on the RC and provide risk to the PC/TP if they do not respond
- Reducing the 6 month period to something like “outages spanning the entire season under study” would be reasonable. Limitations that arise due to shorter term outages are an operating horizon issue mitigated by operating practices, not a planning horizon issue.

The planning assessments are for the Planning Horizon while the RC acts within the Operations Horizon and should not be coordinating the content of planning studies for a disconnected timeframe. Furthermore, this adds a significant burden to the RC and may reduce their focus on more immediate operations.

The language of R1.1.2. also does not provide a clear definition of what types of outages must be considered (e.g. breakers, switches, equipment out for maintenance, etc.).

Long Duong - Public Utility District No. 1 of Snohomish County - 1

Answer	No
Document Name	
Comment	

To require close coordination effort with RCs for outages with a duration of at least six months would be a challenge for base case updates since most planned outages listed on the Coordinated Outage System were tentative plans. Timing and sequential updates would be extremely onerous for PCs and TPs and would be duplicative with operating case development. It would be more practical for SNPD to only review and update base cases to represent system configurations as expected for its annual TPL studies.

BPA has the same comments we had during the unofficial comment period. BPA agrees with moving away from the 6-month fixed duration outages.

However, BPA does not agree that consultation with the Reliability Coordinator is necessary. BPA believes the extra coordination would be burdensome and would not provide additional value. BPA already participates in a 45 day regional outage coordination process. BPA believes that this regional coordination process is sufficient to identify the outages to meet Requirement 1, Part 1.1.2. BPA's Planning group studies seasons, anything shorter than 3 months seems more like an operational issue than a planning issue. With a duration of only 3 months, there's a possibility that the outage may not occur simultaneously with the peak for the season. This would not enhance reliability.

The new requirement is open ended and may result in Transmission Planners (TP) performing almost a "real time" operations analysis (i.e. what is the impact of this outage / what about that outage) in-lieu of designing the Bulk Electric System (the purpose of TPL-001). NERC IRO-017 Outage Coordination was set up for that purpose, and this proposed change would represent a spillover from IRO-017. The TP would be required to develop a Corrective Action Plan for system outages.

The new requirement does not address a scenario where the TP does not agree with the RC regarding what needs to be studied, or how such a disagreement would be managed from the compliance perspective.

We recommend the Requirements 1.1.2 be revised as follows to clarify which entity has the sole responsibility to select the outages (additions in **BOLD**):

R1.1.2 Known outage(s) of generation or Transmission Facility(ies) as selected **by the Transmission Planner following** consultation with the Reliability Coordinator for the Near-Term **Transmission** Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

Alternatively RC should be removed from these Requirements and TP should have the flexibility to select what needs to be studied; as it relates to outages.

In addition, this new requirement would result in Transmission Planners (TP) performing an annual study as the RC could request a study to review upcoming outages. This could result in a conflict with the existing Requirements that allow the use of past studies to satisfy compliance with TPL-001.

This new "consultation" requirement necessitates a correspondence documentation trail that further burdens TP and PC compliance with this already overly complex standard. It is administrative in nature and provides no benefit to the reliability of the BES. We believe that the TP and PC are just as capable to select from the known outages as the RC, and that any consultation with the RC should be at the TP's or PC's discretion.

In addition, while AEP does not object outright to the proposed change that the outages be determined as a result of consultation between the PC/TP and RC, we wonder if such an approach might perhaps lead to inconsistent application and methodologies across the system? The Standards Drafting Team may wish to consider this possibility themselves, and weigh the likelihood of such inconsistencies.

NIPSCO believes any potential issues associated with planned maintenance outages are best identified through operational studies such as real time, next-day, and seasonal analysis rather than through the annual TPL-001-4 system performance analysis. Planned maintenance outages are almost always of short duration and are commonly scheduled to avoid occurrence during critical peak seasons. Only planned maintenance outages which are reasonably expected to occur during critical peak seasons, such as those six months or longer, should be included in the annual TPL-001-4 system performance analysis.

Removing the existing six month threshold for planned maintenance outages and continually reducing the time of duration requires the analysis of an ever greater number of concurrent generator and line outages beyond any specified in the TPL-001-4 standard including (P2) bus+breaker fault, (P4) stuck breaker, and (P7) common tower. This moves the performance analysis requirements of the TPL-001-4 standard closer to an effective N-2 requirement, which is currently an Extreme event, which was never intended.

Further, clarification needs to be given on the meaning of "consultation" and who has the final responsibility of what outage (if any) needs to included in the study models.

Comment

AZPS does not agree with the proposed changes to Requirement 1, Part 1.1.2. AZPS asserts that, giving due consideration to Requirement R4 of IRO-017-1, which came after FERC Order 786, the need to revision Part 1.1.2 has been mooted and is no longer necessary. For this reason, AZPS recommends removal of this requirement.

More specifically, Requirements R3 and R4 of IRO-017 already require coordination between the PC, TP and RC regarding outages in the planning assessment and also requires jointly developed solutions. Thus, the coordination contemplated in Requirement 1, Part 1.1.2 should have already occurred and should not need or be required to re-occur. In fact, AZPS respectfully asserts that the earlier outage and solution coordination occurring as a result of IRO-017 sets up exactly the right process in terms of timing to ensure that outages and solutions are timely, appropriately, and rigorously evaluated. Allowing this coordination to occur in the natural course of operations and not requiring redundant coordination will result in more touch points among the identified entities, facilitating a greater mutual understanding of those outages that would be more impactful to the BES, which understanding better informs the assumptions shaping the inclusion of outages as required by Requirement 1, Part 1.1.2.

For this reason, AZPS respectfully asserts that the coordination and joint solution development requirement included in Requirement 1, Part 1.1.2 be deleted. The inclusion of another coordination and joint solution development beyond that which is required by IRO-017 is not only redundant, but introduces the potential for confusion and ambiguity. Further, the creation of an additional obligation for RC, TP and PC coordination and joint solution development would be simply redundant and would not add enough value to reliability to justify the additional expenditure of resources. Finally, revisiting previous outage coordination and joint solution development would not be cost-effective for any of the involved entities. AZPS recommends removal of the requirement for outage coordination and joint solution development as set forth in Requirement 1, Part 1.1.2.

AZPS further recommends (this is only if deletion is not acceptable) that, since coordination and joint solution development are already occurring under IRO-017, the language of Requirement 1, Part 1.1.2 be revised to state a definitive time period. AZPS respectfully suggests that a 3 month time period for outages is a conservative time period for the inclusion of outages and recommends this time frame as it is generally aligns with those outage time frames that would be considered impactful in the performance of seasonal studies. AZPS recommends the following revisions:

1.1.2 Known outage(s) of generation or Transmission Facility(ies) with a duration of three months for the Near -Term Planning Ho for analysis pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

If the language is retained as it is, AZPS respectfully requests that the RC be added as an applicable functional entity to this standard as there is nothing to obligate the Reliability Coordinator to respond within a required period of time, which could affect the Transmission Provider or Planning Coordinator's ability to complete the work in time.

Joe McClung - JEA - 1,3,5 - FRCC, Group Name JEA Voters

Answer	No
Document Name	

Comment

The proposed TPL-001-5 standard is applicable only to PC and TP per the Applicability section. But RC is NOT under compliance requirement for this action since the standard is NOT applicable to them. The proposed changes add extra burden on the PC and TP for compliance on which they have no control. Any inaction from RC (non-consultation) can expose PC and TP to possible violation with this part of the requirement.

Moreover, the outage coordination seems to be more of an Operational Planning issue (from the next-day studies up to a year out) than a Transmission Planning issue (beyond year one to year ten studies). No matter how far ahead PC and TP study the system, when it comes to the Operation horizon, the outages need to be studied again with a more realistic system conditions than in the Planning Horizon. Hence any specific analyses performed by PC and TP for the outages in the Planning Horizon don't provide much value to the system operators in the Operation horizon.

Additionally, if the system can't meet the performance requirements due to outages as per R2.1.3 and R2.4.3, the TP and PC have no other allowed mitigation plans, such as operational procedures, except to recommend Corrective Action Plans which result in capital improvement projects. Thus planning for outages in the Near-term Transmission Planning Horizon will only result in capital investment that effect the rates of our customers unnecessarily.

Instead IRO-017 Outage Coordination standard is a much better venue to address FERC's concern from Paragraph 40 of Order No. 786 and TPL-001 standard should be maintained solely as a true Transmission Planning Standard. Besides, this directive pre-dates IRO-017 standard and is not relevant anymore under the proposed TPL-001-5 for outage coordination with durations less than six months. Suggestion: Keep the existing language of R1.1.2 unchanged from TPL-001-4 and address Paragraph 40 directive with revision of IRO-017.

We believe that any reference to the RC should be removed from this planning standard. Order 786, paragraph 42, clearly states to "include **known** genertor and transmission planned maintenance outages in planning assessments, not hypothetical planned outages." The RC at best has clear visibility of "known" outages for a period of less than one year. The state of the transmission system in the RC environment is based on "real-time" conditions, which are not conducive of conditions reflected in planning models used in assessments for the near-term or the long-term planning horizons. We suggest changing the language of the requirement to "Known outage(s) of generation or Transmission Facility(ies) occuring within the timeframe of the seasonal models or scenarios used in the analyses, pursuant to Requirement 2, parts 2.1.3 and 2.4.3." This allows for the modeling of "known" outages in any model during both peak and off-peak conditions, which include timeframes when maintenance on transmission facilities can take place based on the models which are developed.

We do not agree with the change to Requirement 1, Part 1.1.2. The Planning Coordinator and Transmission Planners have the capability and understanding to select outages that should be included in their Near-term Planning horizon. For those Reliability Coordinators with a significant number of TPs and PCs in their footprint, this requirement change would add a significant burden on the RCs without benefit to the process. The focus of the RC is in the real-time to one year horizon, whereas Transmission Planning should be focused on the one year to five year horizon. If there needs to be an entity to oversee and advise the TPL studies conducted by the TP, it should be the role of the PC. In addition, these studies are already being performed in the operational arena, therefore there is no benefit in recreating this analysis in the planning horizon. Even if problems were found in the planning horizon, the corrective action(s) would be to forego the outage or to create an op guide. The	

operational cases have a more accurate near-term load/generation profile which are more appropriate for these studies. Recreating these studies in the planning horizon would add no value, but take siginificant new effort and time to complete.

NVE agrees that outages of less than 6 months should be considered, but does not agree that consultaion with the RC is necessary. A list of outages is provided to the RC by an entity, this consultation would require the entity get that list back and ask them to confirm that we should be studying those particular outages. Further, depending on the number of TP's/PC's, asking the RC to consult with each of them could place an unreasonable burden on the RC and place risk to the PC/TP if they do not respond and also necessitates a documentation trail that would further burden the PC/TP. NVE suggests changing the requirement to outages that span the season under study or other outages as determined by the TP/PC.

WAPA understands that the drafting team has chosen this language in an attempt to provide flexibility to the TPs and PCs conducting their TPL Assesment. WAPA supports the need to change the language due to the concern of missing potential critical outages of equipment because the outage does not fall within the "duration of at least six months". If there are known critical outages that cannot be taken out of service under a significant portion of the year (ex: even under light load levels), a Corrective Action Plan is reasonable. In other words, WAPA supports that a properly planned transmission system should ensure that the known planned removal of facilities for maintenance purposes can occur without the loss of non-consequential load or detrimental impacts to system reliability. The concern is that with the existing proposed language, what information is the RC going to provide for this requirement? Will it be a dump of all non-concurrent outages that are scheduled, which may require the TP/PC conducting the TPL Assessment to spend unneccary efforts in justifying why a specific outage should not be included in a TPL study model? Furthermore, RC's likely will not have knowledge of critical outages that could occur further into the future, but are still within the near term planning horizon (up to 60 months into the future). In reality, for the purposes of TPL studies, it is these critical outages further into the future that are important because when identifying areas where Corrective Action Plans are needed it is important to identify them with sufficient lead time available to implement them.	

A possible suggestion to consider would be to change the language by saying that the System models shall represent known critical planned maintenance outage(s) of generation or Transmission Facility(ies) that are expected to have a detrimental impact to system reliability in the Near-Term Planning Horizon for analysis pursuant to Requirement R2, parts 2.1.3 and 3.4.3. The rationale for those critical outage(s) selected for inclusion shall be available as supporting information.

The concept of known or planned outages needs to have a footnote or further explanation to clarify that this applies to “outages needed to execute the CAP” and be very specific. Maintenance outages should not be addressed in this TPL standard. Maintenance outages are typically not known much more than 6 months out and are assessed by Operations Planning, under TOP and/or IRO standards, closer to the desired time of the maintenance outage such that expected system conditions reflected in the study power flow is better known. Our expereince in outage planning has shown that it is very unlikely that “planned” transmission outages exist beyond the next six months and that generator outage schedules are changed frequently. Additionally, to model outages that are expected to last a few weeks to two months into power flow cases that can cover 2-4 months is problematic. The reason is that multiple “potential impactful outages” will likely be identified as canidates to include in the base system power flow model. However, in reality these outages probably don’t overlap thus presenting a complication in selecting what to include in the base system power flow model. Operations Planning builds cases on a daily and weekly basis to assess the impact of planned outages whilch is not practical in the TPL arena. If the Standard stated outages that span the duration of the season being studied that would make this straight forward and remove the RC. While we recognize that the RC is not an applicable entity in this draft of the standard, involving the RC at all in the Requirements is not appropriate either. The responsibility of the RC is “operation” of the system. Any outages in the operating time-frame should have been submitted and reviewed prior to approval. If the RC remains included in the Requirement, need to add words to make it clear that the TP/PC can choose to include the exclusion of stability studies of known outages that might impact steady state but clearly don’t impact stability. Examples might be areas of the transmission system that is not electrically close to generation and not in an area susceptible to FIDVR

We agree with the change except that the Requirement should specifically quantify the time period in which the known outage(s) must be scheduled in order to be considered by the RC, PC, and TP. We feel that Requirement 1, Part 1.1.2 should be written as:

Known outage(s) of generation or Transmission Facility(ies) expected to occur beginning after 12-months from the start of an assessment and beginning before the end of the Near-Term Planning Horizon, as selected in consultation with the Reliability Coordinator for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

This requirement places an additional burden on the PC, TP, and RC without any demonstrated benefit to system reliability. Any outage that would be studied as part of the Planning Assessment would be beyond the Operational Planning time horizon. The concept of performing outage planning as part of a Planning Assessment would be difficult to accomplish. In general, maintenance outages are scheduled to minimize the impacts to the system. Depending on the entity's Off-Peak conditions it may be appropriate to include a planned maintenance outage that occurs at regular intervals. However, the RC would not have any insight into how each individual GO and TO schedules maintenance outages. PNM recommends the FERC approach of removing the 6 month threshold from the requirement.

Additionally, the standard as written does not make clear what CAP would be expected if an entity's planned outage results in a system performance violation? Would the standard permit an acceptable CAP to delay the outage or would the standard require transmission improvements are made to address any system performance violations? PNMR recommends the SDT consider making necessary changes to address these ambiguities.

The RC should use IRO-017 to address any concerns they have about planned outage which might mean expanding operations studies to include multiple category events from TPL-001-4.

CenterPoint Energy disagrees with the proposed changes to Requirement 1, Part 1.1.2 that the outages represented in System models be selected “in consultation with” Reliability Coordinators (RCs). CenterPoint Energy recommends that Reliability Coordinators (RCs) not be added as an applicable Functional Entity. CenterPoint Energy recommends that TPL-001-5 be applicable only to Planning Coordinators (PCs) and Transmission Planners (TPs). CenterPoint Energy recommends deleting the reference to Reliability Coordinators (RCs) in Part 1.1.2 as follows: “Known outage(s) of generation or Transmission Facility(ies) for the Near Term Planning Horizon irement R2, parts 2.1.3 and 2.4.3.”

We feel that the proposed language is too subjective and open to interpretation. The idea of “consulting” with the RC to identify known outages adds to the lack of objectivity in identifying known outages and increases the level of complexity in identifying known outages. We believe this concept does not provide clear compliance ownership for the identification of known outages and believe this will make demonstration of compliance by the Transmission Planner unduly complex.

Comment
The aspects of the current TPL-001-4 and proposed TPL-001-5 standards that address the area of planned maintenance outages mischaracterize the role of transmission planning – which is to provide for an orderly transmission expansion program that ensures the transmission system is adequate, reliable, and resilient at all times in the future given the lead times associated with making necessary system improvements. Adequacy, reliability, and resiliency include the flexibility of a transmission system to allow for the planned outage of any single transmission facility during non-peak periods in a manner that i) does not require the curtailment of firm load and ii) provides for the system to be operated in an N-1 secure state after the single

transmission facility has been removed from service for planned maintenance. All transmission facilities require planned outages from time-to-time to facilitate i) maintenance, testing, and/or repair work that cannot be performed hot; ii) to facilitate protection scheme testing, maintenance, and upgrades on facilities with non-redundant protection; iii) to facilitate capital upgrades to the transmission system or other facilities in the vicinity of the transmission facility; or iv) for other purposes. Therefore, the eventual occurrence of a future planned outage on any transmission facility is certain and "known", not "hypothetical", only the timing and duration of the future outage could be considered uncertain or "hypothetical".   If the transmission system is not planned in a manner that allows for any single facility to be removed for maintenance under non-peak conditions, then the system will not maintain the necessary adequacy and resiliency to accommodate planned maintenance requirements in general.

In FERC Order 786, the Commission indicated the following at PP 41:

"We agree with commenters such as MISO and ATCLLC that certain elements may be so critical that, when taken out of service for system maintenance or to facilitate a new capital project, a subsequent unplanned outage initiated by a single-event could result in the loss of non-consequential load or may have a detrimental impact to the bulk electric system reliability. A properly planned transmission system should ensure the known, planned removal of facilities (i.e., generation, transmission or protection system facilities) for maintenance purposes without the loss of non-consequential load or detrimental impacts to system reliability such as cascading, voltage instability or uncontrolled islanding." (emphasis added)

It is "known" that every transmission facility will eventually need to be taken out of service for planned maintenance or other purposes, thus the prudent planning approach to planned maintenance outages should be to ensure that the transmission system is planned with sufficient robustness and resiliency to accommodate planned maintenance outages during off-peak periods that will be required regardless of whether or not such activity has been scheduled.

Direction on ensuring the system could meet TPL criteria for future potential planned outages was previously given in an interpretation to TPL-002 and TPL-003. Please consider this, as its intent appears to be lost in forming the TPL-001-4 and TPL-001-5 standards.

http://www.nerc.com/docs/standards/sar/MISO_Interpretation_TPL_Revised_20Mar08.pdf

http://www.nerc.com/files/TPL-002-2b.pdf Pg 11

"The following interpretation of TPL-002-0 and TPL-003-0 Requirement R1.3.12 was developed by the NERC Planning Committee on March 13, 2008:

This provision was not previously interpreted by NERC since its approval by FERC and other regulatory authorities. TPL-002-0 and TPL-003-0 explicitly provide that the inclusion of planned (including maintenance) outages of any bulk electric equipment at demand levels for which the planned outages are required. For studies that include planned outages, compliance with the contingency assessment for TPL-002-0 and TPL-003-0 as outlined in Table 1 would include any necessary system adjustments which might be required to accommodate planned outages since a planned outage is not a "contingency" as defined in the *NERC Glossary of Terms Used in Standards."*

While some have argued that outages can be fully managed by outage coordination efforts focused on the operating horizon, if the system is not planned and expanded to maintain sufficient adequacy and resiliency to support future outages, the outage coordination functions may be backed into a corner where there is no choice but to shed load to accommodate an outage or deny an outage given the inability of the outage coordination function to make the necessary system upgrades in the operating horizon that should have been made by the planning function within the planning horizon. An important function of planning is to support operations, which includes ensuring the system is adequate and robust enough to provide flexibility to the outage coordination function to schedule planned outages when they are needed without sacrificing reliability or load continuity.

A proposed remedy would be to expand the P3 and P6 contingency definitions to evaluate an additional multiple outage scenario with no load loss. This scenario would include a planned outage, system adjustments, and then a contingency, but no consequential or non-consequential load loss would be allowed for the planned outage element, and no non-consequential load loss would be allowed for the contingent element. This scenario would be evaluated only for non-peak conditions. The idea here is that the system does not need to be planned to support planned maintenance during peak load conditions, since those conditions represent a very small percentage of time. However, under periods where planned maintenance is typically performed (e.g., shoulder peak and light load conditions, etc.), the system should be planned to accommodate the planned outage of any one system element (transmission or generation) while ensuring the system can continue to operate in a manner that is N-1 secure with no non-consequential load loss. This additional aspect of the P3 and P6 contingencies will require an adjustment to the traditional contingency definitions to facilitate service to all loads for the planned maintenance outage element in accordance with how the system would be switched for planned maintenance. For example, the planned maintenance outage of a network transmission line section with tapped distribution substations served by the line would be switch-to-switch (only the section between two adjacent distribution substations that required maintenance would be taken out of service) instead of breaker-to-breaker to ensure all load could continue to be served during the planned maintenance outage. This change to the standard ensures that there is a minimal level of flexibility to provide for the planned outage of any single element in the system, which better aligns with the overall goal of transmission planning to ensure the system is adequate, resilient, and reliable in the future.

The new requirement is open ended and may result in Transmission Planners (TP) performing almost a “real time” operations analysis (i.e. what is the impact of this outage / what about that outage) in-lieu of designing the Bulk Electric System (the purpose of TPL-001). NERC IRO-017 Outage Coordination was set up for that purpose, and this proposed change would represent a spillover from IRO-017. The TP would be required to develop a Corrective Action Plan for system outages.

The new requirement does not address a scenario where the TP does not agree with the RC regarding what needs to be studied, or how such a disagreement would be managed from the compliance perspective.

We recommend the Requirements 1.1.2 be revised as follows to clarify which entity has the sole responsibility to select the outages (additions in RED):

R1.1.2 Known outage(s) of generation or Transmission Facility(ies) as selected by the Transmission Planner following consultation with the Reliability Coordinator for the Near-Term Transmission Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

Alternatively RC should be removed from these Requirements and TP should have the flexibility to select what needs to be studied; as it relates to outages.

In addition, this new requirement would result in Transmission Planners (TP) performing an annual study as the RC could request a study to review upcoming outages. This could result in a conflict with the existing Requirements that allow the use of past studies to satisfy compliance with TPL-001.

We agree with the change except that the Requirement should specifically quantify the time period in which the known outage(s) must be scheduled in order to be considered by the RC, PC, and TP. We feel that Requirement 1, Part 1.1.2 should be written as:

Known outage(s) of generation or Transmission Facility(ies) expected to occur beginning after 12-months from the start of an assessment and beginning before the end of the Near-Term Planning Horizon, as selected in consultation with the Reliability Coordinator for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

While the probability of an unplanned contingency during a short duration (less than six month) planned outage is much lower than during a longer planned maintenance outage period, these types of scenarios are already evaluated and planned for in the TPL-001-4 planning assessment through the various N-1-1 contingency combinations. It is PacifiCorp's opinion that the short-term planned outage scenarios are better addressed in the operating horizon. Also see WAPA's comments.

Duke Energy re-affirms its concern with adding short term outages to these planning assessments. As written, this standard requires that a PC must consult with the RC and possibly include in studies short term outages with which the PC has no input on or have any responsibility for outside of this requirement. This is better suited in the Operations Planning horizon based on the operational and dynamic nature of outages with a duration of at least six months.

1. We believe the SDT is heading in the right direction with the proposed modification. However, the accountability of the RC in the consultation process does not reflect what is already required in NERC Reliability Standard IRO-017-1. As proposed, a PC or TP would need to incorporate any planned outage it became aware of in its Planning Assessment, even if the outage has not yet been processed in an impacted Reliability Coordinator's outage coordination program. Requirement R4 of NERC Reliability Standard IRO-017-1 does require the TP and PC to develop, jointly with their RCs, solutions that resolve issues identified from planned outages included in a Planning Assessment. Moreover, what proof is necessary to demonstrate an applicable entity consulted their RC? Most entities will likely extract approved outage information from a database and not through verbal or electronic communication with their RC. We propose rewording Requirement 1, Part 1.1.2, of the proposed Reliability Standard TPL-001-5 to "outage(s) of generation or Transmission Facility(ies) identified through implementation of its Reliability Coordinator's outage coordination process.
2. We ask the SDT to specify the appropriate RC that should influence an impacted PC's or TP's system model and Planning Assessment. Currently, the proposed language opens the possibility that any RC could provide information regarding a generation or Transmission Facility outage.

Due to the large number of Planning Coordinators and Transmission Planners in the Reliability Coordinator area, this would be too much of a burden on the RCs to provide appropriate feedback without causing a significant delay or setting the threshhold too low where most if not all planned outages which would significantly increase the time needed to complete the assessment. If the 6 month requirement is removed, the PCs/TPs should provide a reason those planned outages were selected. This would be similar to the language allowing the PCs/TPs to determine which Planning Events are selected to evaluate.

Comment	

The proposed requirement in part 1.1.2 of R1 that TPs and PCs select known outages "in consultation with" their Reliability Coordinators for use in developing planning models creates unnecessary ambiguity. TPs and PCs already have the ability to obtain information about known outages under MOD-032, and TPs and PCs already use that authority in complying with the requirement to include known outages greater than six months long in their planning assessments. So involving the RC in identifying outages for planning models is unnecessary. The "in consultation with" phrasing is also unclear as to the particular efforts required by the TP, PC, and RC. Who bears the burden for the initial communication? What if the RC fails to provide some or all of the outage information? If the RC and TP/PC disagree as to which outages should be included, whose opinion controls? The SRC recommends eliminating this proposed language and instead clarifying the standard to give the TP/PC clear deference in deciding which expected outages should be included in the various planning models. The SRC recommends the following language for part 1.1.2:

1.1.2. Known outage(s) of generation or Transmission Facility(ies) selected by the Transmission Planner or Planning Coordinator in its sole discretion for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3.

The SRC notes that IRO-017, R4, already requires that "[e]ach Planning Coordinator and Transmission Planner shall jointly develop solutions with its respective Reliability Coordinator(s) for identified issues or conflicts with planned outages in its Planning Assessment for

the Near-Term Transmission Planning Horizon." The SRC recommends removing or clarifying this requirement in a future project, since transmission planning requirements should be captured in the TPL standards and because the RC should, as a general rule, have no role in transmission planning activities.

Note: MISO and ISO-NE do not support this comment.

Comment

The RC is not a Functional Entity in the TPL-001-5 Applicability and has no obligation to comply with this standard. The definition of RC states that the RC prevents/mitigates "operating situations in both next-day analysis and real-time operations." The RCs role is in the operations horizon, not the planning horizon. Thus, RCs should not be consulted for outages represented in the planning horizon, which is beyond the scope of their duties. Including this requirement would add additional burden to entities which would now have to coordinate numerous outages with the RC. This additional step will add risk for entities to comply with this standard as it is another form of communication that may not be fulfilled (as in the RC may not respond). The RC would also have the unreasonable burden of coordinating with numerous entities.

Furthermore, this language does not prevent the RC from requesting hypothetical outages. An RC may request that an outage of a critical facility to be studied during peak conditions, when it is the TO's practice to only take this outage during off-peak conditions due to that very reason. While the use of only "real" known outages is FERC's intent, there is no language in the proposed standard to prevent the RC from requesting a hypothetical outage.

In WECC, the Peak RC COS outage management tool used by the RC does not frequently capture outages out into the planning horizon. Additionally, the Peak RC has implemented an outage coordination process to evaluate outages in the operations horizon to manage these risks.

It is important to understand that much like protection system relaying is both a science and an art, one cannot fully study outages without understanding the nature of outage coordination. CHPD's planning engineers work both on planning studies and operational studies, so we are aware that some outages are planned in the future, but when evaluated, simply won't work under those conditions. The proper mitigation, rather than to create a new project to fix this, is to move the outage to a time when it will work or cause more manageable impacts.

Based on FERC's comments under order 786, paragraph 41, the intent of this re-visit on the 6 month criteria is to address "a single element to be taken out of service for maintenance without compromising the ability of the system to meet demand without loss of load." Given that this is FERC's area of focus, the NERC criteria may consider a criteria in-line with those ends, such as requiring outages that the RC has identified that have required loss of load based on past operational experience. NERC may also consider allowing system adjustments for these outages, as is common with actual operational practice.

Based on FERC's suggestions, a reduced window or definition of a "significant planned outage based, for example, on MW or facility ratings" would be preferred over the outright removal of the 6 month window and the Peak RC additions currently proposed.

We agree with reducing the duration of known outages from at least 6 months to at least 3 months. However, based on current practices and considering this proposed reduction, it is still doubtful that there would be any planned transmission outages to consider for inclusion in the models for the planning horizon. We do not believe that involving the Reliability Coordinator would lead to any fruitful discussions from a planning perspective.

In WECC, the Peak RC COS outage management tool used by the RC does not frequently capture outages out into the planning horizon. Additionally, the Peak RC has implemented an outage coordination process to evaluate outages in the operations horizon to manage these risks.

It is important to understand that much like protection system relaying is both a science and an art, one cannot fully study outages without understanding the nature of outage coordination. CHPD’s planning engineers work both on planning studies and operational studies, so we are aware that some outages are planned in the future, but when evaluated, simply won’t work under those conditions. The proper mitigation, rather than to create a new project to fix this, is to move the outage to a time when it will work or cause more manageable impacts.

Based on FERC’s comments under order 786, paragraph 41, the intent of this re-visit on the 6 month criteria is to address “a single element to be taken out of service for maintenance without compromising the ability of the system to meet demand without loss of load.” Given that this is FERC’s area of focus, the NERC criteria may consider a criteria in-line with those ends, such as requiring outages that the RC has identified that have required loss of load based on past operational experience. NERC may also consider allowing system adjustments for these outages, as is common with actual operational practice.

Based on FERC's suggestions, a reduced window or definition of a "significant planned outage based, for example, on MW or facility ratings" would be preferred over the outright removal of the 6 month window and the Peak RC additions currently proposed.

Comment

The RC is not a Functional Entity in the TPL-001-5 Applicability and has no obligation to comply with this standard. The definition of RC states that the RC prevents/mitigates "operating situations in both next-day analysis and real-time operations." The RCs role is in the operations horizon, not the planning horizon. Thus, RCs should not be consulted for outages represented in the planning horizon, which is beyond the scope of their duties. Including this requirement would add additional burden to entities which would now have to coordinate numerous outages with the RC. This additional step will add risk for entities to comply with this standard as it is another form of communication that may not be fulfilled (as in the RC may not respond). The RC would also have the unreasonable burden of coordinating with numerous entities.

Furthermore, this language does not prevent the RC from requesting hypothetical outages. An RC may request that an outage of a critical facility to be studied during peak conditions, when it is the TO's practice to only take this outage during off-peak conditions due to that very reason. While the use of only "real" known outages is FERC's intent, there is no language in the proposed standard to prevent the RC from requesting a hypothetical outage.

In WECC, the Peak RC COS outage management tool used by the RC does not frequently capture outages out into the planning horizon. Additionally, the Peak RC has implemented an outage coordination process to evaluate outages in the operations horizon to manage these risks.

It is important to understand that much like protection system relaying is both a science and an art, one cannot fully study outages without understanding the nature of outage coordination. CHPD's planning engineers work both on planning studies and operational studies, so we are aware that some outages are planned in the future, but when evaluated, simply won't work under those conditions. The proper mitigation, rather than to create a new project to fix this, is to move the outage to a time when it will work or cause more manageable impacts.

For ease of implementation and efficiency and compliance, a bright line criteria such as “at least six months” is appropriate. There is little reliability risk for outages shorter than this duration and the burden imposed by the coordination requirement is not worth the cost.

Requirement 1, Part 1.1.2 seems to imply that the outages that are selected by the Planning Coordinator (PC)/Transmission Planner (TP) in consultation with their Reliability Coordinators (RCs) should be baked in to the System Models. However, Requirement 2, Part 2.1.3 and Part 2.4.3 indicate that only P1 events should be run on the cases with these outages in place. So, should the outages be removed to perform the studies required under Parts 2.4.1, 2.4.2, and 2.4.4 where we are required to consider P1-P7 and Extreme events? This is a point of the confusion in the current standard as well and we would ask the standard drafting to please clarify.

ITC believes all combinations (N-1-1) should be considered in planning studies for load levels up to those at which the system is typically maintained. It is imperative that the system is planned so that it can be adequately maintained. While ITC agrees with the proposed changes in outages that should be represented in system models to those selected by the PC/TP in consultation with the RC, ITC feels this would be better if included in IRO-017. ITC also agrees with the proposed changes in outages that should be represented in system models to those selected by the PC/TP in consultation with the RC however ITC feels this would be better if included in IRO-017.

Comment

Texas RE does not necessarily agree the drafting team met the intent of FERC Order 786, Paragraph 40, which states "…we direct NERC to modify Reliability Standard TPL-001-4 to address the concern that the six month threshold could exclude maintenance outages of significant facilities from future planning assessments." The proposed language allows excessive flexibility between the RC and TP/PC, especially considering the RC and PC are frequently the same entity. At the very least, Texas RE recommends a criteria be developed with technical justification for long term outages that need to be modeled as well as criteria to determine which maintenance outages need to be studied. The proposed language could result in not selecting any outages and the entities would still be compliant.

8. Do you agree with omitting the Reliability Coordinator (RC) from the applicability of the TPL-001-5 standard given that Requirement R1, Part1.1.2 requires consultation between the TP/PC and the RC to determine which known outages to select for representation in System models?

Shannon Mickens - Southwest Power Pool, Inc. (RTO) - 2 - SPP RE, Group Name SPP Standards Review Group	
Answer	No
Document Name	
Comment	
The SPP Standards Review Group recommends that the drafting team develop some language that includes the Transmission Owners (TOs) and Generation Owners (GOs) to help close the gap on known outages that are outside of the Operating Horizon to be included in Part 1.1.2. However, if the drafting team feels that developing language to include the TO and GO is not the appropriate action, we would also suggest considering IRO-017 as another option to pursue.

Robert Ganley - Long Island Power Authority - 1

Answer	No
Document Name	

Comment

As stated in our comment above, We feel that the proposed language is too subjective and open to interpretation. We believe the proposed language for 1.1.2 does not provide clear compliance ownership for the identification of known outages.

While the draft language places an obligation on the TP/PC to consult, there is no obligation on the RC to respond. What if the RC does not respond or provide timely input? Is the TP/PC held non-compliant for having no planned outages included in the planning assessment?

Response

Armin Klusman - CenterPoint Energy Houston Electric, LLC - 1 - Texas RE

Answer	No
Document Name	

Comment

CenterPoint Energy recommends Reliability Coordinators (RCs) not be added as an applicable Functional Entity. CenterPoint Energy recommends that TPL-001-5 be applicable only to Planning Coordinators (PCs) and Transmission Planners (TPs). CenterPoint Energy disagrees with the proposed changes to Requirement 1, Part 1.1.2 that the outages represented in System models be selected “in consultation with” Reliability Coordinators (RCs).

CenterPoint Energy recommends deleting the reference to Reliability Coordinators (RCs) in Part 1.1.2 as follows:

“Known outage(s) of generation or Transmission Facility(ies) for the Near
and 2.4.3.”

The SDT should consider the situation in the TRE Region where ERCOT is both the PC and the RC. Planned outages are not firmly determined until a few months before they are expected to be implemented. ERCOT currently has no input into a TP's annual assessment until such a time that construction requiring an outage is requested. PNMR views this as a potential Operational issue which should be studied at the appropriate time before requesting/taking an outage. Longer lead-time outage timing can be difficult to reliably include in planning studies due to the degree of unknown variables, such project delays, conflicting outage schedules, and as such may not be able to be reasonably included in long-term planning assessments. Further, PNMR recommends including the RC Registration Function in the Standard's applicability given the RC has responsibilities under the standard.

AZPS only agrees with omitting the Reliability Coordinator if R.1.1.2 is deleted as suggested or modified such that it does not require consultation with the Reliability Coordinator as stated above in response to question 7. If the language is retained as is, AZPS respectfully requests that the RC be added as an applicable functional entity to this standard. Unless the standard is applicable to RCs, there is nothing to obligate the Reliability Coordinator to respond within a required period of time, which could affect the Transmission Provider or Planning Coordinator's ability to complete the assessment work in time. AZPS reiterates its comments provided in response to Question 7.

If the SDT does not accept our comment to clarify and revise R1.1.2, then then the applicability of TPL-001 must be expanded to include the RC, to ensure the RC "consults" with the TP. TO and GO that own Protection Systems should be added to applicability, so that those entities are required to provide the necessary Protection System information to the Transmission Planner so the TP can perform the Planning Analysis.

Yes. This is a Planning Standard and the RC does not need to be involved as stated in the response to question 7. However, if the RC involvement remains, they should be included in applicability and should have a time requirement to respond (5 business days) to respond to the Planning Coordinator (PC) or Transmission Planner (TP) if they are in agreement with the maintenance outages to be studied as proposed by the PC/TP.

As noted in the SRC's response to Question 7, above, the language of part 1.1.2, as proposed, is unclear as to the degree to which it requires any action of the RC. If the standard is clarified to give the TP/PC sole discretion in selecting the outages, then the RC has no role in this process, and there is no need to worry about whether the RC should be listed among the entities to whom the standard applies. **Note: ISO-NE does not support this comment.**

9. FERC Order No. 786 Paragraphs 40-45 direct modification to address significant planned maintenance outages with durations less than 6 months in planning assessments. Are you aware of an existing standard/requirement, consistent with industry practice and applicability that requires review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in System models (TPL 001-4 Requirement R1 Part R1.1.2)?

Ginette Lacasse - Seattle City Light - 1,3,4,5,6 - WECC, Group Name Seattle City Light Ballot Body

Answer	No
Document Name	

Comment

No we are not aware of any other standards/requirements that meet these stipulations. However, to reiterate the response and suggestion from Question 7: reducing the 6 month period to something like “outages spanning the entire season under study” would be reasonable. Limitations that arise due to shorter term outages are an operating horizon issue mitigated by operating practices, not a planning horizon issue.

SNPD is not aware of an existing Standard/Requirement, consistent with industry practice and applicability, that requires review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in system models. This newly suggested Requirement is not practical for PCs and TPs to consider. SNPD obtained initial cases from WECC-approved cases with anticipated topology, system loads and generation. SNPD reviewed and updated these cases based on budget-approved and projected transmission line projects, projected generation resources, and forecasted peak demand data. When a long-term outage (more than 6-12 months) is being planned and needs to be considered for a selected study case, we will update the case to reflect the intended plan for All-Lines-in-Service ("ALIS") N-0 conditions.

No, CHPD is not aware of any other standards/requirements that require review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in System models.

CHPD currently studies shorter term outages in the Operational Planning Assessment (daily study), the Short Range Study, and seasonal studies as outlined in the Peak RC methodologies. Issues due to short term outages are studied and mitigated in the operations horizon, not the planning horizon. Outages that should be included in the planning horizon should be outages with a duration spanning the entire study window but not any shorter as these are addressed in the operations horizon.

The challenge with this requirement is that this supports the system models used in an entity's system assessment. The more outages to be included in this analysis, the more models an entity must use in order to support this requirement. Multiple model maintenance to support multiple outages can quickly become a potentially burdensome issue.

The idea of a "planned maintenance outage" has currently begun to be addressed under the IRO-017 standard.

Outage planning in the operations horizon can and does identify when outages won't work during a particular season due to system constraints. Outage planning can also help identify when multiple unintentionally overlapping outages would lead to system issues. Requiring these sorts of outage planning activities to also be carried out in the transmission planning assessment will increase burden to entities as there may need to be numerous studies run to identify issues and full outage details are not always firm. It is common practice in operations to mitigate these by re-scheduling the outage. This is a much more cost-effective solution than implementing capital projects to support outages which have not been fully planned out into the Planning Horizon.

As mentioned above in AZPS's response to Questions 7 and 8, IRO-017-1 R3 and R4, essentially meets the intent of TPL 001-4 Requirement R1 Part R1.1.2. AZPS asserts that, giving due consideration to Requirements R3 and R4 of IRO-017-1, which came after FERC order 786, that Part 1.1.2 is not needed. We would recommend removal of this requirement because R3 and R4 of IRO-017 requires coordination between the PC, TP and RC on outages in the planning assessment and also requires jointly developed solutions. These requirements for coordination and joint solution development associated with outages moots the issue being addressed through the addition of this language. To create an additional obligation for RC, TP and PC coordination would be redundant and would not add value to reliability that would justify the additional expenditure of resources.

The SPP Standards Review Group recommends that the drafting team develop language that will include the Transmission Owners (TOs) and Generation Owners (GOs) to help the modeling process as well as ensuring that those particular entities are included into the applicability section of the standard as well. Also, we recommend the drafting team develop a Requirement that would clearly and definitively explains those entities' responsibilities. However, if the drafting team feels that developing language to include the TO and GO is not the appropriate action, we would also suggest considering IRO-017 as another option to pursue.

Duke Energy cannot agree with a 36 month implementation period. The ambiguity that exist on what constitutes “redundancy” of a protection system component makes it difficult to determine what an appropriate amount of time would be. As written, the standard will require assessments by entities to check components of all protection systems for redundancy, without defining in a clear manner what that redundancy is or should look like. Depending on additional guidance on what redundancy would be, the amount of time that would be needed to do redundancy identification could increase the amount of time necessary to comply with this standard. Without having that clarity, we cannot agree to the proposed 36 month implementation plan.

For utilities having a larger system, a 48 month implementation plan would be preferable to perform a comprehensive field survey of all single points of failure and establish coordination with protection engineers. It also allows additional time to perform the single points of failure analysis required by the standard.

Addressing all new requirements (except 4.2 and 2.7) which would include the new spare equipment strategy for the stability analysis and addressing outages per consultation with the RC, may require a period longer than 36 months. Stability analysis is the most time consuming part of the planning assessment so the additional portion to analyze the spare equipment strategy will take some time to develop. Coordinating outages with the RC will also be very time consuming as there is currently no process in place and the RC will have to correspond with numerous entities regarding numerous outages that have the potential to be in scope.

Addressing all new requirements (except 4.2 and 2.7) which would include the new spare equipment strategy for the stability analysis and addressing outages per consultation with the RC, may require a period longer than 36 months. Stability analysis is the most time consuming part of the planning assessment so the additional portion to analyze the spare equipment strategy will take some time to develop. Coordinating outages with the RC will also be very time consuming as there is currently no process in place and the RC will have to correspond with numerous entities regarding numerous outages that have the potential to be in scope.

The 36 month implementation plan is reasonable for developing a process with protection engineers to assess single points of failure. The RC process is not necessary.

Mike Smith - Manitoba Hydro - 1	
Answer	No
Document Name	
Comment	
The additional 24 months to implement any resulting Corrective Action Plans for P5 events may be too short. Requirement 4.2 should only be a study requirement and have 36 months to complete. There should be no requirement to implement a Corrective Action Plan for extreme events.

BPA is concerned that because the system was not designed for extreme events, the fix could be rather intensive requiring a lot of effort and a lengthy lead time to implement. 60 months may not be long enough. BPA believes the focus should be about reducing the likelihood, not preventing it.

Answer	No
Document Name	
Comment	

The new language under Requirement R4, Part 4.2.2 and both the subparts 4.2.2.1 and 4.2.2.2 should be deleted all together. It goes far beyond what the conclusion from the analysis from Order No. 754 recommended and will cost the industry a very significant amount of time and money for implementation for a comparatively insignificant improvement in the reliability. Requirement R4, Part 4.2 subpart 4.2.1 already addresses the Cascading issue for extreme events in the Commission approved and currently enforceable TPL-001-4 standard and should be left as-is.

We agree that for the Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4 events, the system still needs to perform reliably and without any planning criteria violation. However, no operational workaround can be performed for any newly identified violation due to this suggested/clarified language for Footnote 13 and capital improvement projects will be the “only” corrective action plans which will require a significant time and effort for coordination among PCs, TPs and the Facility owners and operators (TO/ TOP/ GO/ GOP). In addition, the installation/ implementation of such Corrective Action Plans may cost the industry tens of billions of dollars with significant construction effort spanning 10-20 years. Hence a mere 60 months (5 years) for meeting Requirement 2, Part 2.7 associated with P5 due to Footnote 13 bullets 2, 3 and 4 implementation and compliance is not adequate and seems too aggressive. The industry needs to be surveyed again to see the outcome from the studies with the modified/clarified language in 5 years (after 36 months for TPL-001-5 effective date + 24 months to develop corrective action plan) to have a more realistic implementation schedule for the remedies (Corrective Action Plans) for Part 2.7.

Suggestion: Part 4.2.2 and both the subparts 4.2.2.1 and 4.2.2.2 under Requirement 4, Part 4.2 is not needed since Requirement R4, Part 4.2 – 4.2.1 already addresses it. Regarding Requirement 2, Part 2.7, an additional industry survey shall be conducted to determine a reasonable and appropriate timeline to implement the Corrective Action Plans just for the newly identified shortcomings for P5 events with the proposed/modified Footnote 13.

A 72 month implementation plan would be preferable for the development of Corrective Action Plans under TPL-001-5 to address newly-added studies involving single points of failure on Protection Systems. This would allow additional time for utilities with a larger system and the coordination of outages for implementing Corrective Action Plans.

Answer	No

Document Name	
Comment	
We do not agree with the 60 month implementation plan for projects to address the modified P5 events. These changes will require extensive work in order to make protection systems completely redundant for P5 events, requiring switch houses in some cases. If several switch houses are required, 60 months would not provide adequate time to complete the corrective action plans.

Since we have significant concerns with the proposed 4.2.2 language and with the ambiguity of the proposed P5 event / Footnote 13 (see our comments to question #1, #2, #4 and 6), we feel it is premature to consider a specific implementation plan that involves that event. We cannot agree to a proposed implementation plan for an event that needs clarification.

Texas RE noticed that Requirement 4, part 4.2 is not called out by name in the implementation plan. The extra 24 months is only mentioned in the General Considerations section and not in the section under Effective Date. It is not clear which requirement the extra 24 months applies to, nor is clear that entities are actually given an extra 24 months as it is not mentioned in the Effective Date section. To clarify these actions need to be done by a certain time, **Texas RE recommends the Effective Date section specify all dates by which all actions need to be completed, organized by requirement number.**

In addition, Texas RE suggests that the monitoring and reporting should be aligned with PRC-005-6 attributes moving forward. If this adjustment is made, the only additional step required by entities would be:

- Identify protective relays without an alternative that provides comparable Normal Clearing times (13.1).
- Identify communication system and dc supply, including monitoring alarming attributes (would already be required for PRC-005-6).
- Identify control circuitry (already required for PRC-005-6).
- Define contingencies for the failure non-redundant components.

There is no reason to believe that these steps could not be accomplished by the effective date of TPL-001-5 and would not need an additional 24 months.

Comment	
Oncor believes the extreme events for Requirement 4, Part 4.2 and Requirement 2, Part 2.7 associated with the modified P5 events should not warrant any timetable for developing a Corrective Action Plan. These events are extremely unlikely and would cost Oncor capital project dollars that could have been spent on much more likely events such as single-phase faults with delayed clearing.

12. In looking at all proposed recommendations from the standard drafting team, are the proposed changes a cost effective approach which meets the FERC directives? (*see* *Cost Effectiveness Background Document*)

Gary Trent - Unisource - Tucson Electric Power Co. - 1 - WECC	
Answer	No
Document Name	
Comment	
Involving the Reliability Coordinator will extend the time necessary to evaluate planned maintenance outages which will reduce cost effectiveness. Planned outages are currently evaluated in the Operating Horizon so this results in at least doubling the effort to evaluate planned outages. A bullet listing of the FERC directives would have been beneficial for this question so additional time would not have been required to search the FERC Order to determine all the FERC directives.

Per our response to question 10, depending on what the definition of redundancy actually is, the cost to implement, and become compliant with this standard could be significant. More information as to redundancy is needed.

No, GTC is concerned that the standard implies CAPs are to be created for extreme events. This would not only be cost ineffective, it would be a heavily burdened standard which would not result in the desired reliability benefits.

New Part 4.2.2 – The obligation to evaluate the new extreme stability 2e-2h event contingencies, go significantly beyond the Part 4.2.1 obligations for all other extreme events and are not expected to be cost effective. The 2e-2h contingencies are classified as extreme events, but Part 4.2.2 requires actions beyond the Part 4.2.1 obligations for the other extreme events, namely the development of a list of possible actions to prevent Cascading, a timetable for implementation of the possible actions, and annual continued review of the implement status and validity of the possible actions. No justification has been provided to justify the expenditure of significantly more time and resources for the new 2e-2h contingencies

SCE agrees that all proposals are the cost-effective approach except one proposal. With respect to SCE's comments for Question 6 regarding Footnote 13d, SCE believes that the intention of the proposed TPL-001-5 to require fully-redundant control circuitry without due consideration of status monitoring combined with periodic independent component testing is duplicative for system reliability and is not the most cost-effective option to address the FERC directive. SCE proposes that the cost-effective solution includes the allowance for excluding control circuitry with montioring from footnote 13 d.

New Part 2.4.3 – This obligation to study P1 events for known outage conditions is expected to be cost effective. New Part 4.2.1 – This obligation is a relocation of the existing second obligation in Part 4.5 of the TPL-001-4 standard and expected to still be cost effective. New Part 4.2.2 – The obligation to evaluate the new extreme stability 2e-2h event contingencies, go significantly beyond the Part 4.2.1 obligations for all other extreme events and are not expected to be cost effective. The 2e-2h contingencies are classified as extreme events, but Part 4.2.2 requires actions beyond the Part 4.2.1 obligations for the other extreme events, namely the development of a list of possible actions to prevent Cascading, a timetable for implementation of the possible actions, and annual continued review of the implement status and validity of the possible actions. No justification has been provided to justify the expenditure of significantly more time and resources for the new 2e-2h contingencies. Footnote 13 4 – The obligation to evaluate single control circuit failures is expected to be cost effective, if our recommendation to replace reference to trip coils is replaced with a reference to control circuit auxiliary relays is implemented. Otherwise, the simulation of trip coil failures is not expected to be cost effective because it will be duplicative of a P4 category event simulation, and therefore, unnecessary

The obligation to mitigate the new extreme stability 2e-2h event contingencies, goes significantly beyond the Part 4.2.1 obligations for all other extreme events. WAPA does not believe that the cost/benefit will be reasonable because the frequency of these SPF events are so seldom, they do not warrant the cost to eliminate them. No data has been provided to demonstrate that SPFs have been a significant factor in system outages.

We do not believe the proposed changes to footnote 13 as well as the addition of a corrective action plan requirement for extreme events are a cost effective approach. Including the control circuitry associated with the protective functions would cause a large financial burden to retrofit existing stations, or construct new switch houses, for those stations which fail criteria. Requiring mitigations or corrective action plans for extreme events, which have a very low probability of occurring, would also have a large financial impact with very little impact on system reliability.

Not only some of the proposed recommendations from the SDT are cost-prohibitive, but the added reliability benefit is miniscule as compared to the cost and the aggressive implementation schedule that will be needed to achieve the desired outcome. A more reasonable approach is needed to	

address the directives. The suggestions in the above questions go a long way to achive a very good balance between the cost effectiveness and realiability of the power system.

In particular, the proposed recommendation of the standard drafting team regarding the removal of the 6 month window does not represent a cost effective approach due to the lack of a timeframe. This could open the door to numerous un-coordinated outages whose impacts could be better mitigated through outage coordination in the operational timeframe under the existing IRO-017 requirements.

The new spare equipment strategy for stability analysis against P1 and P2 contingencies does not represent a cost effective implementation either. FERC's language in order 786 paragraph 89 states "However, the Commission will not direct a change and instead directs NERC to consider a similar spare equipment strategy for stability analysis upon the next review cycle of Reliability Standard TPL-001-4". In CHPD's experience, the impacts that the steady state analysis was trying to evaluate were thermal and voltage violation in nature; thus to analyze the loss of equipment that provided this function on the system, such as large power transformers, made sense. However, stability simulations, in our experience, are more strongly impacted by clearing times. Therefore, the spare equipment analysis that is useful for the steady state analysis does not typically modify these clearing times, and thus will not likely yield meaningful results to the degree that it does for the steady state analysis. NERC may consider additional language or guidance regarding the stability application of the new spare equipment strategy to better focus its application to those contingencies where clearing times and as a result, stability could be impacted by the loss of the spare equipment.

Lastly, the proposed changes will add burden to entities and could result in great costs for potentially documenting and implementing mitigation for cascading due to Extreme Events.

FERC has directed that the effects of non-redundant components of a system protection system be evaluated. While not all issues of non-redundant parts of a non-redundant propective system are evaluated, the significant items are to be studied. If cascading occurs, a project should be identified.

Comment	
We wish to change this to YES. This TPL-001-5 update should coordinate with the proposed changes to FAC-010, FAC-014 and the new FAC-015 standards. Specifically, the requirements in FAC-015 specify what system operating limits should be used in planning assessments. Standard TPL-001 covers all other requirements relating to planning assessments. Having a separate standard defining the limits that should be used in planning studies adds unnecessary complication and potential for confusion, therefore these new FAC-015 requirements should be included within TPL-001-5. The fact that both of these standards are being updated now should be taken advantage of so that there are no reliability gaps.

The proposed TPL-001-5 requires implementation of capital projects, which directly conflicts with our provincial regulations. We cannot legally adopt this standard. MH will have to review the final changes in detail to determine what to implement as a MH standard.

The language of 4.2.2. can be construed as requiring implementation of of corrective actions which include capital projects and additional infrastructure. Such a requirement would contradict the Energy Poicy Act of 2005, specifically the section below: **Energy Policy Act of 2005** **TITLE XII—ELECTRICITY** **Subtitle A—Reliability Standards** **SEC. 1211. ELECTRIC RELIABILITY STANDARDS** **SEC. 215. ELECTRIC RELIABILITY** ''(2) This section does not authorize the ERO or the Commission to order the construction of additional generation or transmission capacity or to set and enforce compliance with standards for adequacy or safety of electric facilities or services."

Due to the changes incorporated in this proposed TPL standard, Reliability Standard CIP-014-2 – Physical Security can be impacted with the outcome. The proposed TPL-001-5 is setting the bar higher than before for the PC and TP. This can result in a different scenario for applicable Transmission Facilities for CIP-014-2 as identified by PC and TP (CIP-014-2 – section 4. Applicability – 4.1. Functional Entities – 4.1.1 – 4.1.1.3) in accordance with the proposed TPL-001-5 analyses.

If monitoring of Protection System components is counted for purposes of TPL-001-5, is it the drafting team's intent that an entity would be obligated to maintain the alarming paths and monitoring systems under PRC-005-6 (Requirement R1, Part 1.2, and Table 2)? An entity should be allowed to consider monitoring for purposes of TPL-001-5 but treat the associated Protection System component(s) as unmonitored for purposes of PRC-005-6.

We wish to change this to YES. *R1.1.2. Known outage(s) of generation or Transmission Facility(ies) as selected in consultation with the Reliability Coordinator for the Near-Term Planning Horizon for analyses pursuant to Requirement R2, parts 2.1.3 and 2.4.3..* SCL comments: The requirement does not clarify who selects the outages to be included in the study. Will it be at TP's discretion, or will all the outages proposed by the RC be included in the study(ies)? Also, the language did not specify the duration of the outage as selected in consultation with the RC. SCL's previous recommendation calls for outage that fall within the entire season of the planning horizon under study.

We agree that Footnote 13 is an improvement over the previous. However there are still some ambiguities that should be clarified either directly or through appropriate descriptions in the rationale boxes or supplementary material section. We believe ambiguities may lead to confusion during the necessary Protection System assessments, or unnecessary expenditures by entities. 13.b Please clarify wording on “a single communication system (…) which is not monitored or reported”. Please clarify if the intent is that a “single monitored communication system” means that a single communication channel which is monitored and reported meets the redundancy requirement. 13.c - Please clarify the term “open circuit” and provide an example (in the supplementary material). An open circuit in the battery system can be caused by many things, such as loose connections at the battery or any downstream DC breaker/fuse opening. Is it the intent of this footnote to capture only the opening of the main protective device (breaker/fuse) after the DC system? If so, the following wording is offered as suggestion: “13.c A single DC supply associated with protection functions, and that single station DC supply is not monitored or not reported, either directly or indirectly, for both low voltage and for interruption of the total station DC supply by any immediate downstream protective device.” We believe this wording along with appropriate rationale and an example would help clarify this footnote.

1. We ask the SDT to identify VSLs for Requirement R8. 2. The Standards Authorization Request associated with this project provides the SDT an opportunity to evaluate requirement retirements under Paragraph 81 criteria. We believe Requirements R5, R6, R7, and R8 fall under such criteria. Documenting acceptable voltage limit deviations are all necessary, yet are likely documented as assumptions and technical rationales listed within Planning Assessments. Moreover, these criteria are not directly associated with the required execution of conducting studies. The identification of study coordination roles and responsibilities through meeting minutes and distribution of Planning Assessment results to appropriate entities within a specific time period are administrative activities. Further proof is that these requirements do not have performance-based VSLs identified. We ask the SDT to review these standards and identify reasons why Paragraph 81 criteria do not apply. 3. We thank you for this opportunity to provide these comments.

Colby Bellville - Duke Energy - 1,3,5,6 - FRCC,SERC,RF, Group Name Duke Energy	
Answer	Yes
Document Name	
Comment	
Duke Energy suggests that objectives outlined in the FERC Directives could be accomplished without the need to revise the standard in this manner. The objectives could be met in the form of a NERC project or initiative requesting that these assessements/studies be done in 10% or 20% intervals over a set period of time, and the data submitted to NERC for its review. We feel that requiring these objectives in a standard, with the ever changing	

configuration of the system, would require that this work as proposed be done every year, which would be extremely burdensome. We recommend that the studies and assessments that will be required would be better suited outside of the NERC standards.

Answer	Yes
Document Name	
Comment	

TPL-001-5 R8 should include distribution to impacted RCs and IRO-017-1 R3 be removed.

Traditionally the intent of "extreme events" or "extreme contingencies" was to create awareness of the impacts of the studied contingencies, but not establish design requiements. Therefore we recommend moving Table 1 Extreme Events Stability elements 2e through 2h from the Extreme Events table to Table 1 Planning Events, under a new Category P8, with the following attributes:

Category: P8 Multiple Contingency

Initial Condition: Normal System

Event: 2e through 2h

Fault Type: 3 phase

BES Level: HV, EHV

Interruption of Firm Transmission Service Allowed: Yes

Non-Consequential Load Loss Allowed: Yes

With this change, Requirement R4.6 should be revised as follows: " If the analysis concludes there is Cascading caused by the occurrence of Table 1 planning events P8, a Corrective Action Plan shall be developed….."

The definition of "Near-Term Transmission Planning Horizon" needs to be clearly documented in the NERC Glossary of Terms. The current definition of "The transmission planning period that covers Year One through five" is not without ambiguity as the meaning of 'covering Year One' is not universally agreed upon.

The definition of "Year One" in the NERC Glossary of Terms is defined as

The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For an assessment started in a given calendar year, Year One includes the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One includes the forecasted peak Load period for either 2012 or 2013.

If a Transmission Planner begins an assessment in January of 2011, Year One would include the peak load for 2012 (August) which is 19-months in the future or for 2013 which is 31-months in the future. If a Transmission Planner begins an assessment in December of 2011, Year One would include the peak load for 2012 (August) which is 8-months in the future or for 2013 which is 20-months in the future.

'Year One' covering a time period of as short as 8-months or as long as 31-months is not clear and will lead to misunderstandings and different interpretations of NERC Requirements. We propose that 'Year One' should be defined as:

The time period of the first twelve months beginning on the date an assessment is started.

The definition of "Near-Term Transmission Planning Horizon" would then be completely clarified if it was defined as:

The transmission planning period that begins with the end of Year One and continues through the next four forecasted peak Load periods.

The definition of "Long-Term Transmission Planning Horizon" would also be completely clarified if I   t was defined as:

The transmission planning period that begins with the fifth forecasted peak Load period and continues through the tenth forecasted peak Load period (or beyond when required to accommodate any known longer lead time projects that may take longer than ten years to complete).

Additionally, all of the time periods (such as "Long-term Planning", "Operations Planning", "Same-day Operations", "Real-time Operations", and "Operations Assessment") described and defined in the NERC document "Time Horizons" (most recently modified in 2014) should be moved into the NERC Glossary of Terms.

There is no mention of instrument transformer failure as a single component failure, but such failures could directly result in a failure to trip and thus subsequent reliance on delayed remote backup protection to clear the fault. A NERC technical paper titled “Protection System Reliability – Redundancy of Protection System Elements”, which was prepared by the NERC System Protection and Control Subcommittee and dated November 18, 2008, correctly indicates that instrument transformers can represent a single point of failure in a protection system as follows:

From Section 5.1 of the technical paper: “At least two isolated and separate AC current sources (referred to as CT inputs) for Protection Systems are required to meet the proposed requirement for CT redundancy. Figure 5-3 shows a common arrangement that addresses the current measurement redundancy requirement. CTs are required to provide totally separate secondary AC current sources for each redundant Protection System. This is required so that a shorted, open, or otherwise failed CT circuit will not remove all protection elements requiring current.”

From Section 5.2 of the technical paper: “At least two separate secondary

windings supplying voltages for Protection Systems are required to meet the proposed requirement for AC voltage source redundancy when such voltage sources are required to satisfy the BES performance required in the TPL standards. This is required so that a shorted, open, or otherwise failed voltage circuit will not remove all protection elements requiring voltage.”

The proposed requirements outlined in the NERC technical paper align well with how most transmission owners have historically developed fully redundant protection schemes, and thus should be incorporated into Footnote 13 of the proposed TPL-001-5 standard.

Unless the SDT has statistical data that supports the notion that the probability of an instrument transformer failure is much lower than the probability of other failure modes identified in Footnote 13, Footnote 13 should be expanded to include instrument transformers, or at a very minimum, current transformers and voltage transformers with single secondary windings.

Additional Comment for consideration, related to clarification of the Standard:

Regarding Table 1, if the performance requirements (steady state / stability) are not being met, AND, if Table 1 indicates that non-consequential load loss and interruption of Firm Transmission Service are allowed, is a specific corrective action plan required as per Requirement 2.7 (assuming that non-consequential load loss and/or interruption of Firm Transmission Service would allow for meeting the performance requirements)? This question relates to a scenario where Footnote 12 does not apply. A general recommendation is to clarify within the standard whether or not a specific corrective action plan is required to be documented, as per Requirement 2.7, in the Planning Assessment for this scenario (i.e. performance requirements are not being met and Footnote 12 does not apply).

Additional Comment for consideration, related to Requirement #4 (related to clarification of the Standard):

Requirement 4.1 states that “Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1…..” Immediately after 4.1, sub-requirements 4.1.1 through 4.1.3 specify specific system/generator stability performance requirements which are not mentioned in Table 1. Our observation is that Table 1 includes steady state and stability related performance requirements. This apparent placement of performance requirements in more than one location within the Standard document is confusing. Recommendation for consideration is to move sub-requirements 4.1.1 through 4.1.3 to Table 1.

We proposed the following general recommendations.

1. Footnote 13 – For the introductory sentence, we suggest; “If the following components of a Protection System are not redundant, then failure of one component must be evaluated”.

2. Footnote 13 – Add text to Footnote 13 to explicitly note in the standard that CTs and VTs used by Protection Systems are not to be considered as applicable to Category 5 events. After the list of the four types of applicable comments, we suggest adding; “Current instrument transformers (CTs) and voltage instrument transformers (VTs) used by the Protection System are not to be considered as applicable Protection System components for P5 category events.

Comment	
FMPA cannot support the standard revision with the addition of 2.4.3 as it is currently worded. FMPA pointed out in the previous comment period that the language used effectively eliminates the ability to apply engineering judgement to study those events that are expected to produce more significant impacts in the Stability analysis portion of the Planning Assessment. As currently worded, 2.4.3 would required Stability analysis of all P1 events which would result in a tremendous amount of work, but very little benifical insight, since P1 events are typically much less severe from a stability perspective. While comments indicating that proposed methods are "too much work" are not often taken very seriously, due to the fact that R2.4 is in reference to the Stability analysis, the amount of additional work, especially for some larger Planning Coordinators and Transmission Planners, could be completely infeasible to simulate and to thoroughly review results (log files and plots). FMPA believes the intent of the drafting team was to capture stability issues related to "known outages", but has unintentionally gone well beyond that. FMPA supports the drafting team exploring whether IRO-017 is the appropriate standard to address FERC's concerns regarding planned outages, but at a minimum believes 2.4.3 needs to be reworded. FMPA suggests an approach very similar to the language used in 2.4.5 to address this issue (i.e. – "selected P1 events….expected to produce more servere System impacts…").

PNMR recommends that R8 should be revised to include the impacted Reliability Coordinators. With this revision, PNMR believes that IRO-017-1 R3 could be retired as this standard would accomplish the intended reliability objective and would reduce the administrative burden on PCs and TPs. PNMR further recommends that R4 from IRO-017-1 be added to TPL-001-5 R2.7 since it is requiring the CAP be developed with the RC. In addition, the SDT should consider adding the RC as an applicable entity. With this revision, IRO-017-1 R4 could be retired as this standard would accomplish the intended reliability objective. The intention of R2.4.3, as written, is unclear. Is the intention to require known outages be included in the assessment of System peak and Off-Peak conditions? The requirement should be revised to clearly define what is required to be in compliance.

The definition of “Near-Term Transmission Planning Horizon” needs to be clearly documented in the NERC Glossary of Terms. The current definition of “The transmission planning period that covers Year One through five” is not without ambiguity as the meaning of ‘covering Year One’ is not universally agreed upon.

The definition of “Year One” in the NERC Glossary of Terms is defined as

The first twelve month period that a Planning Coordinator or a Transmission Planner is responsible for assessing. For an assessment started in a given calendar year, Year One includes the forecasted peak Load period for one of the following two calendar years. For example, if a Planning Assessment was started in 2011, then Year One includes the forecasted peak Load period for either 2012 or 2013.

If a Transmission Planner begins an assessment in January of 2011, Year One would include the peak load for 2012 (August) which is 19-months in the future or for 2013 which is 31-months in the future. If a Transmission Planner begins an assessment in December of 2011, Year One would include the peak load for 2012 (August) which is 8-months in the future or for 2013 which is 20-months in the future.

‘Year One’ covering a time period of as short as 8-months or as long as 31-months is not clear and will lead to misunderstandings and different interpretations of NERC Requirements. We propose that ‘Year One’ should be defined as:

The time period of the first twelve months beginning on the date an assessment is started.

The definition of “Near-Term Transmission Planning Horizon” would then be completely clarified if it was defined as:

The transmission planning period that begins with the end of Year One and continues through the next four forecasted peak Load periods.

The definition of “Long-Term Transmission Planning Horizon” would also be completely clarified if it was defined as:

The transmission planning period that begins with the fifth forecasted peak Load period and continues through the tenth forecasted peak Load period (or beyond when required to accommodate any known longer lead time projects that may take longer than ten years to complete).

Additionally, all of the time periods (such as “Long-term Planning”, “Operations Planning”, “Same-day Operations”, “Real-time Operations”, and “Operations Assessment”) described and defined in the NERC document “Time Horizons” (most recently modified in 2014) should be moved into the NERC Glossary of Terms.

The current draft of the standard seems to straddle the fence between Planning Events and Extreme Events for the performance requirements of Items 2e – 2h. Thus, we suggest that 2e – 2h be placed in one or the other. Our recommendation is to not require a CAP.

If the intent is to not require a CAP, it should be inserted into the Extreme Events category but with the same performance requirements as all the other Extreme Events (i.e., assessment of determining strategies to manage cascading which don’t have to be implemented should not be required).

If the intent is to require a CAP, which we do not recommend, other alternatives include:

The requirements in the Extreme Events Table 2e-h should be depicted in Table 1 Planning Events as a second Row of P5 with three-phase as the “fault-type” for several reasons:

1.
    i. Table 1 note (a) already covers “cascading” not being allowed – maybe eliminating the need for a new R4.6 altogether
    ii. Clearly shows this as a signitifcant “raising-the-bar” event requiring a CAP
    iii. Maintains the separation between Planning Events (requiring a CAP) and Extreme Events (requiring analysis and optional CAP)

An alternative to it being depicted as a second row of P5 with three-phase as the “fault type” could be to make a P8 for stability only.

R2.4.5: Need some verbiage to allow for excluding studies of unavailable equipment that might impact steady state but clearly don't impact stability. Examples might be areas of the transmission system that are not electrically close to generation and not in an area susceptible to FIDVR. An extra sentence "Analysis, including simulations as detailed in R2.4.5, are required only for scenarios where a stability impact could be possible as a result the unavailable equipment" or something similiar would be appropriate. If clarifying verbiage is not included, the result would be the need to devote countless manhours to perform studies that will provide no reliability value.

Suggest changing "Table 1 – Steady State & Stability Performance Extreme Events" to "Table 2 – Steady State & Stability Performance Extreme Events" as these are two separate tables.

The rationale to include 3 phase faults with the failure a non redundant component of a Protection System is too onerous (Extreme Events Table – stability 2e – 2h). This scenario with a SLG fault is onerous enough

We proposed the following general recommendations.

Footnote 13 – For the introductory sentence, we suggest; "If the following components of a Protection System are not redundant, then failure of one component must be evaluated".

Footnote 13 – Add text to Footnote 13 to explicitly note in the standard that CTs and VTs used by Protection Systems are not to be considered as applicable to Category 5 events. After the list of the four types of applicable comments, we suggest adding; "Current instrument transformers (CTs) and voltage instrument transformers (VTs) used by the Protection System are not to be considered as applicable Protection System components for P5 category events.

NVE has some additional comments regarding stability analysis for an entities spare equipment strategy. NVE would like to see some additional language regarding the selection of selected P1 and P2 category events. Perhaps language similar to what is in R4.4 would help to add some clarifying language as to which P1 and P2 contingencies shoud be studied for the spare equipment analysis.

Extreme events 2e – 2h involves studying 3 phase faults on various elements with a failure of a non-redundant component of a protection system. In the presence of a protection system single point of failure, this fault type may not be the most critical. Since most modern protection systems are designed using a higher lever of redundancy, the extreme events described in 2e – 2h will be most applicable to legacy protection systems. Many of these legacy protection systems use single phase electromechanical or solid state relays. With a three phase fault, failure of a single relay would not impact the ability to detect and clear a fault since the relays on the other phases would detect and intitiate clearing as though no relay failure had occurred. For a line to ground fault with a failed relay on that phase, the fault would need to detected and cleared through other means and result in delayed clearing. For a line to ground fault that develops into a three phase fault and mentioned in the technical rationale document, as soon as the fault developed into a three phase fault, the other relays would detect the fault and then clear as appropriate. A line to ground fault would either have to wait to develop into a three phase fault to be cleared or wait until remote relays detect and clear the fault. It would then appear that the line to ground fault with a failed relay would have a greater impact than a three phase fault with a failed relay. NVE recommends that the extreme event 2e – 2h be modified to line to ground faults or something along the lines of “if the non-redundant protection systems is implemented using single phase or ground relays, the 2e – 2h element faults must also be studied for single line to ground faults with delayed clearing.

We again appreciate all the hardwork and expertise of SDT for this project. The data request and analysis after Order No. 754 was a good first step towards addressing the single points of failure in the protection system and the proposed language in TPL-001-5 is an improvement upon that criteria. The SDT is headed in the right direction and with some additional guidance/suggestion from the industry; as received during the prior informal comment opportunity and this formal comment period; the directives from FERC and concerns from the SPCS and the SAMS can be easily achieved with minimal burden to the rate payers/customers of the electric power industry but with significant improvement in the reliability of Bulk Power System.

AEP is concerned that this project and the proposed revisions go beyond the SAR in a number of ways. Of greatest concern is the inclusion of Footnote 13b (communication systems) and the inference of a Corrective Action Plan in R 4.2.2 (originally provided as R 4.6 in draft 1 from the informal comment period). Because the SAR's scope and direction did not include these topics, we believe these proposed revisions should be removed.

Traditionally the intent of "extreme events" or "extreme contingencies" was to create awareness of the impacts of the studied contingencies, but not establish design requiements. Therefore we recommend moving Table 1 Extreme Events Stability elements 2e through 2h from the Extreme Events table to Table 1 Planning Events, under a new Category P8, with the following attributes: Category: P8 Multiple Contingency Initial Condition: Normal System Event: 2e through 2h Fault Type: 3 phase BES Level: HV, EHV Interruption of Firm Transmission Service Allowed: Yes Non-Consequential Load Loss Allowed: Yes With this change, Requirement R4.6 should be revised as follows: " If the analysis concludes there is Cascading caused by the occurrence of **Table 1 planning events P8**, a Corrective Action Plan shall be developed….."

Requirement R1, Part 1.1.2 in TPL-001-5 has language that is redundant to IRO-017-1, Requirements R3 and R4. • Both address planned outages in the Near-Term Planning Horizon.	

- Both require the Transmission Planner and Planning Coordinator to consult with the Reliability Coordinator regarding the selection of know generation and Transmission outages for the Near-Term Planning Horizon.

LSPT prefers the team's language changes in TPL-004-5 for planned outage modeling as opposed to the current IRO-017-1 requirements.

Redundant requirements in NERC Reliability Standards are unwarranted. In FERC's order (issued March 15, 2012 in RC11-6-000) in response to NERC's "Find, Fix, Track, and Report" proposal stated, in part, the following in Paragraph 81:

"…. some current requirements likely provide little protection for Bulk-Power System reliability or may be redundant. The Commission is interested in obtaining views on whether such requirements could be removed from the Reliability Standards with little effect on reliability and an increase in efficiency of the ERO compliance program. If NERC believes that specific Reliability Standards or specific requirements within certain Standards should be revised or removed, we invite NERC to make specific proposals to the Commission identifying the Standards or requirements and setting forth in detail the technical basis for its belief."

In response to Paragraph 81, NERC filed (and FERC subsequently approved) the retirement of 34 requirements within 19 Reliability Standards – see Order No. 788, RM13-8-000. These changes were approved with a single Standard Authorization Request ("SAR")

LSPT understands that Project 2010-10's SAR limits the drafting team's scope to changes to TPL-001-4. Therefore, LSPT recommends that the drafting team propose a revision to the SAR that would allow the team the flexibility to address any NERC approved standard with requirements that addresses planned maintenance outage modeling in planning assessments when the team addresses Paragraph 40 in Order 786. (Paragraph 40 directs NERC to modify Reliability Standard TPL-001-4 to address the concern that the six-month threshold could exclude planned maintenance outages of significant facilities from future planning assessments.)

This proposed SAR change is an example only. However, a SAR change is needed to allow the team the flexibility to propose the retirement of IRO-017-1 Requirements R3 and R4 concurrent with the approval of TPL-001-5 Requirement R1, Part 1.1.2.

Comment	

The SPP Standards Review Group feels that an alternative first step should have been in a PRC Standard to address the concerns in reference to Single Point Failure. Furthermore, there could be a potential disconnect between the Transmission Planner and Protection Engineers by placing this only in a Planning Standard. Also, we recommend that the draft team includes the Transmission Owner (TO) and Generator Owner (GO) in the applicability section, along with an additional requirement specifying that the TO and GO should provide pertinent data (e.g., contingency definitions, elements tripped) upon request by the PC in order to assess the impact of Single Point of Failure in their assessments.

Patricia Robertson - BC Hydro and Power Authority - 1,3,5, Group Name BC Hydro	
Answer	Yes
Document Name	
Comment	
BC Hydro appreciates the efforts of the SDT in revising TPL-001-5 – Transmission System Planning Performance Requirements. BC Hydro votes “No” and wishes to provide the following two comments 1. At present BC Hydro is not aware of the process and criteria of Reliability Co-ordinator in identifying planned outages for the Near Horizon assessment pursuant to Requirement R2, parts 2.1.3 and 2.4.3. Accordingly, BC Hydro is not in a position to assess the impact of this modification to the standard.	

2. The proposed amendments scope from Single Point of Failure is very wide, which will apply to the entire bulk electric system i.e. 100 kV and above. Our recommendation would have been affirmative if the scope were limited to extra high voltage (360 kV and above), where a single point of protection failure after a fault can trigger a major system disturbance.

Below extra high voltage levels, BC Hydro protection systems are built using principles of good utility protection practices, as described in the ANSI/IEEE standards and guides, to ensure that they have acceptable reliability i.e. clear faults without mis-operating. Our protection systems are largely redundant but still can have a single point of failure, such as where there is a shared breaker trip coil or a single telecom fibre etc. Based on our fifty years of operating experience, there is no known case where a single point of failure in our high voltage protection system precipitated in a major system disturbance event. It is because probability of a single failure (in our redundant high voltage protection system) impacting our system performance is negligible. Yet demonstrating compliance to the proposed amendments will require BC Hydro to redirect our critical resources (financial and people) in identifying single points of failure in our every single high voltage P&C asset, estimate incremental protection clearing time associated that failure, and then demonstrate acceptable system performance during the event. Instead of redirecting our critical resources to demonstrate compliance to this negligible probability event, BC Hydro will receive higher reliability benefits by continuing to invest our resources in upgrading the aging protection systems.

The new version of the standard has included the spare equipment strategy into the stability portion of the assessment. This is unnecessary because this analysis is captured in the normal stability study. For example, a transformer qualifies as equipment with lead time greater than a year. The loss of the transformer is captured in the normal stability contingency analysis. If this analysis resulted in an unacceptable response, the scenario would be investigated to determine a mitigation (like using a spare transformer in its place).

CHPD would also appreciate extra language in R2.7 confirming that the required Corrective Action Plans are also extended to the spare equipment analysis and the maintenance outage requirements. This is CHPD's understanding, but this is not called out directly in the standard. We would appreciate language in R2.7 supporting NERC's expectation.

We feel that more explanation/guidance is needed to address what is and is not included in the "components of a Protection System." The research to determine which of these components is a single point of failure, and what the delayed clearing time would be, is potentially quite expansive. We would like to have a more clear idea of the scope of this work and how the impacts differ from P4 and the existing P5 contingencies.

Texas RE understands the Note Regarding Corrective Action Plans, the 84 month timeframe, is 84 months from the effective date of TPL-001-4, which was January 1, 2015. By January 1, 2022, the CAPs should no longer include Non-Consequential Load Loss and curtailment of Firm Transmission Service. Texas RE requests justification for that 84 month time period.

Texas RE recommends changing the name of the table with the extreme events to “Table 2”. It is confusing the Table with the planning events and the table with the extreme events are both named “Table 1” and many of the requirements refer to Table 1 even though they refer to different things.

Texas RE also noticed what appears to be a typo for MOD-032 in R1. There is a hyphen before MOD-032 and the font does not match the rest of the standard.

Comments received from Kristine Ward, Seminole Electric Cooperative, Inc.

TPL-001-5 Comments

(1) In reviewing the edits to R1.1.2, SECI is concerned about the vagueness of those outages that must be modeled and whether such consultation will now require the RC to meet with each TP and PC separately within the FRCC on an annual basis.

(2) Given the changes to requirement R1.1.2, we believe there needs to be applicability in the standard to the Reliability Coordinator and not just the PC and TP. Also, since the SDT struck out the duration of six months in R1.1.2, there should be a time-frame around the length of transmission outages given some outages are only for a few hours, some for a day, a week, a month, etc., that may not be covering the year, season, or load level entities are assessing.

(3) In reviewing R1.1.2, the term “Transmission” appears to be need to be inserted into the term “Near-Term *Transmission* Planning Horizon” to be consistent with the defined term in the NERC glossary.

(2) Regarding the edits to R1.1.2, what happens if the RC, TP, or PC disagree as to which outages to include in the System models? Is it acceptable to the SDT if procedures are written whereby not all entities are in agreement with which outages to include?

(3) In R2.1.5, the SDT changed "studied" to "assessed". Can the SDT provide background on what is now expected with the term "assessed" differently than what was performed under the term "studied"?

(4) In R2.4.5, can the SDT elaborate on what is expected in, and how detailed, an entity's spare equipment strategy should be that is needed for TPL-001-5?

(5) In R2.4.5, the wording "The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment" opens entities up to major compliance interpretation issues as it's not certain that entities will evaluate ALL conditions that the System is expected to experience in our Planning Assessment, this needs to be further clarified by the SDT.

(6) P5, and footnote 13, was modified to cover non-redundant components of a Protection System. This is a substantial additional burden onto entities. Seminole requests the team to perform a cost effectiveness study concerning these additional edits.

Project 2015-10 Single Points of Failure

Consideration of Comments

Introduction

The standard drafting team (SDT) appreciates industry comments on the proposed Reliability Standard, TPL-001-5. The SDT considered the comments submitted during the initial posting of the proposed Reliability Standard, and has revised the standard accordingly.

The System Protection and Control Subcommittee (SPCS) and the System Analysis and Modeling Subcommittee (SAMS) conducted an assessment of protection system single points of failure in response to FERC Order No. 754, including analysis of data from the NERC Section 1600 Request for Data or Information. The assessment confirms the existence of a reliability risk associated with single points of failure in protection systems that warrants further action.

Additionally, the two directives from FERC Order No. 786 (p. 40 and p. 89) and updates to the MOD reference in Requirement R1, Measure M1 and the Violation Severity Levels sections have been added to the scope of the project.

Response to Comments – Summary Responses

The SDT has carefully reviewed and considered each stakeholder comment and has revised language where suggested changes are consistent with SDT intent and industry consensus. Also, several commenters suggested non-substantive language changes. The SDT has carefully considered each such comment and has implemented revisions to further clarify the language where needed. The SDT has addressed each comment and has provided below, in summary form, a response to each question.

Consideration of Comments

Project 2015-10 Single Points of Failure | TPL-001-5

Associated Ballots: 2015-10 Single Points of Failure TPL-001-5 IN 1 ST

There were ## sets of responses, including comments from approximately ## different people from approximately ## companies representing # of the 10 Industry Segments as shown in the table on the following pages.

All comments submitted can be reviewed in their original format on the project page.

If you feel that your comment has been overlooked, please let us know immediately. Our goal is to give every comment serious consideration in this process. If you feel there has been an error or omission, you can contact the Senior Director of Standards, Howard Gugel (via email) or at (404) 446-9693.

1. Do you agree that an associated timetable for implementation of actions needed to prevent the System from Cascading (TPL-001-5 Requirement R4, Part 4.2.2.1) and an annual review of implementation status (TPL-001-5 Requirement R4, Part 4.2.2.2) should be required when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

2. Do you agree that the requirements of the proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2, including an implementation timetable and annual review of implementation status, should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading? For example, do you agree that a capital project is not required to be implemented by Requirement R4, Parts 4.2.2.1 and 4.2.2.2, even if the capital project is the only feasible action available to prevent the System from Cascading when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

3. Do you agree with the omission, as proposed in TPL-001-5 Requirement R4, Part 4.2, of a requirement similar to that of Requirement R2, Part 2.7, which states that the planned System shall continue to meet the performance requirements in Table 1 in subsequent Planning Assessments?

4. Do you agree with including Table 1 Footnote 13 a., “[a] single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, *e.g.*, sudden pressure relaying”, and its limitation to only the specific single protective relay and not to other elements of the associated Protection System?

5. Do you agree with the inclusion of Table 1 Footnote 13 b. & c. stipulation, "which is not monitored or not reported", and that it conveys the expectation that the monitoring and reporting is sufficient to result in prompt remediation addressing the failure status of the associated equipment?

6. Do you agree with the inclusion of Table 1 Footnote 13 d., and that it, in conjunction with defined terms, identifies what constitutes all of the elements of, "A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices."?

7. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that modify which known outages shall be represented in System models from those "with a duration of at least six months" to those selected by the Planning Coordinator (PC)/Transmission Planner (TP) "in consultation with" their Reliability Coordinators (RCs).

8. Do you agree with omitting the Reliability Coordinator (RC) from the applicability of the TPL-001-5 standard given that Requirement R1, Part1.1.2 requires consultation between the TP/PC and the RC to determine which known outages to select for representation in System models?

9. FERC Order No. 786 Paragraphs 40-45 direct modification to address significant planned maintenance outages with durations less than 6 months in planning assessments. Are you aware of an existing standard/requirement, consistent with industry practice and applicability that requires review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in System models (TPL 001-4 Requirement R1 Part R1.1.2)?

10. Do you agree with the 36 month implementation period to address all Requirements except for Requirement R4, Part 4.2, and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.

11. Do you agree with the 60 month implementation plan for Requirement 4, Part 4.2 and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.?

12. In looking at all proposed recommendations from the standard drafting team, are the proposed changes a cost effective approach which meets the FERC directives? (*see* *Cost Effectiveness Background Document*)

13. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

14. Do you have any other general recommendations/considerations for the drafting team?

Consideration of Comments – Summary Responses

Question 1: Associated Timetable and Annual Review Requirement R4 Summary Response

1. Do you agree that an associated timetable for implementation of actions needed to prevent the System from Cascading (TPL-001-5 Requirement R4, Part 4.2.2.1) and an annual review of implementation status (TPL-001-5 Requirement R4, Part 4.2.2.2) should be required when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

Extreme Event

There is a suggestion to remove implementation status and timetables, also extreme event 2e – 2h or three-phase fault followed by a protection failure is a low probability event and should have the same requirements as other extreme events.

SDT Response: The SDT agrees to remove implementation status and timetables. However, since FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended three-phase faults be analyzed. Based on the reliability risk, the SDT decided to make the three -phase fault followed by a protection failure a P8 event with no Cascading allowed or a Corrective Action Plan (CAP) requirement.

PRC Standard Requirement

Why this requirement isn't part of the PRC standards, but is instead proposed for standard TPL-001?

SDT Response:

Project 2015-010 SAR does not allow for changes to any NERC standards other than TPL-001.

Requirement of CAP

There appears to be very little difference between 4.2.1 and 4.2.2 other than making a list and establishing an implementation timetable that would be meaningless if there is no intent to implement the solution. The current TPL-001-4 wording is sufficient unless there is a desire to require development and implementation of a Corrective Action Plan for certain events and circumstances, in which case, as previously suggested, the contingency should be moved from the extreme event category to a planning contingency category. Otherwise the wording in the current standard regarding extreme events that are found to result in cascading and/or instability should not be modified. There is confusion or lack of clarity around whether a CAP is required for the extreme event 2e – 2h.

SDT Response:

The SDT agrees to remove implementation status and timetables. However, since FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended three-phase faults be analyzed. Based on the reliability risk, the SDT decided to make the three -phase fault followed by a protection failure a P8 event with no Cascading allowed or a Corrective Action Plan (CAP) requirement.

NERC Glossary Term

“Action” is not a defined term. SDT should write what they mean by “Action”.

SDT Response:
The SDT removed the reference to “Action” other than what is in the NERC Glossary for “Corrective Action Plan”.

CAP for Low Probability Event

It is not economically justifiable to require a CAP for low probability events. The SDT did not consider the cost and other factors.

SDT Response:
FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended three-phase faults be analyzed. Based on the reliability risk, the cost of redundant relays, redundant trip coils, monitoring of communications and/or monitoring of DC supply is lower than the cost of transmission lines or transformers. Adding redundant protection improves the reliability of the Bulk Power System (BPS) at lower costs than other construction projects.

Shunt Devices

Add shunts to the list of 2e-2h list of extreme events.

SDT Response:
The SDT agrees with this and shunts were added to the next version of the standard. However, the SDT decided to make the disturbance a P8 planning event and requiring CAPs.

Transmission Planner Process

The review should follow the designated Transmission Planner’s existing processes that have already been developed. This review should be rolled into that process.

SDT Response:
The SDT agrees and made the event a P8 event which will follow similar reviews and processes as other planning events.

Adjustable Time Frame

Recommend the drafting team adds language to section 4.2.2.2 to clarify during the review process pertaining to the Planning Assessments for continued validity and implementation status that an adjustable time frame would always be taken into consideration.

SDT Response:

The SDT agrees with this and it is addressed by making a three phase fault followed by a protection failure a P8 planning event.

Q1 Additional Comments

Additional Comment #1
Commenter does not agree with separating out the extreme event in 2e-2h for something between a CAP and no CAP.

SDT Response:
Standard Drafting team agrees with this comment and will be making a three-phase fault followed by a protection system failure a P8 planning event.

Additional Comment #2
The term “Planning Assessment” is defined in the NERC Glossary as a “documented evaluation of future Transmission System performance and Corrective Action Plans to remedy identified deficiencies.” We believe these studies should not be used as a tracking mechanism for Corrective Action Plans, and that an adjustable time frame should be considered during subsequent reviews.

SDT Response:
The SDT agrees and made the event a P8 event which will follow similar reviews and processes as other planning events.

Additional Comment #3
No value added in extending the requirement to include event categories 2e-2h.

SDT Response:
FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended a three-phase faults be analyzed. Based on the reliability risk, the cost of redundant relays, redundant trip coils, monitoring of communications and/or monitoring of DC supply is lower than the cost of transmission lines or transformers. Adding redundant protection improves the reliability of the BPS at lower costs than other construction projects.

Additional Comment #4
There is risk with the proposed changes of the single point of failure (SPF) language that will not significantly improve reliability. There is likelihood this change may even reduce reliability by having the CAPs force entities to redirect its limited resources away from other important reliability needs to solve SPF identified issue. Further, implementation of the CAPs may likely cause significant mis-ops while system protection systems are being modified to eliminate SPFs thus reducing reliability and increase risk to the transmission system. We would also like to point out that there is no corresponding directive from FERC in the SAR.

SDT Response:

FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended three-phase faults be analyzed. Based on the reliability risk, the SDT decided to make the three-phase fault followed by a protection failure a P8 event with no Cascading allowed. The costs vs. benefit or resource requirements vs benefit is difficult to quantify since the reliability risk to the BPS is difficult to quantify in costs alone.

Question 2: Associated Timetable and Annual Review Requirement R4 Summary Response

2. Do you agree that the requirements of the proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2, including an implementation timetable and annual review of implementation status, should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading? For example, do you agree that a capital project is not required to be implemented by Requirement R4, Parts 4.2.2.1 and 4.2.2.2, even if the capital project is the only feasible action available to prevent the System from Cascading when analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column?

Project Implementation

Language indirectly mandates implementation of construction of a project. The Requirement (Parts 4.2.2.1 and 4.2.2.2), as written, mandates actual implementation of actions identified as needed to prevent the System from Cascading. Language implies that action must be taken.

This aspect of the standard does not appear to meet the 'Clear Language' criteria in NERC's Standards Quality Review 'QR' Checklist because the requirement language as written does not assure that entities will be "able to arrive at a consistent interpretation of the required performance.

Commenters suggest removing 4.2.2.1 and 4.2.2.2 which may remove the interpretation issues of whether a CAP is required. This is a meaningless exercise if a project is not required.

Commenter recommends that the SDT remove the timetable language and change the language similar to Requirement 4, part 4.2.1 to state "an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences of the event(s) shall be conducted.

There is too much room for interpretation and suggests that a CAP is required.

SDT Response:
The SDT agrees and is removing Parts 4.2.2.1 and 4.2.2.2 but a three-phase fault followed by a protection failure is being moved to a P8 planning event.

Requirement of CAP

Language should be changed to a CAP is required or aligned with other extreme events.

Actions to mitigate protection system single point of failure do not usually incur significant cost. Mitigating single points of failure is the direction from FERC order 754. Changes to this Standard was deemed to be the most effective means to accomplish this objective. If corrective actions (capital projects) are not required by this standard, then the FERC objectives may not be achieved which could lead to additional large scale system events or disturbances and additional FERC orders.

SDT Response:
The SDT agrees and is making the 2e-2h a P8 planning event with a CAP requirement.

Project Implementation
If a capital project is the only feasible action, then it can be interpreted that implementation of the capital project is needed.

It appears that requiring an implementation plan and timetable is similar to a corrective action plan and is being mandated. Until the studies are done, it cannot be determined if any capital projects were included. In general, the utility will determine whether or not to address an issue based on risks and consequences of the event.

SDT Response:
The intent of the SDT was to have more analysis for a 2e-2h event as compared to other extreme events. It was not the intent of the SDT to require a CAP. However, due to industry comment and the risk of reliability to the BPS, the SDT has decided to make a three phase fault followed by a protection failure a planning events or P8.

Requirement of Project Implementation
Requirement 4.2.2 only requires "an evaluation of possible actions designed to prevent the System from Cascading". Requests that if the occurrence of an extreme event (2e-2h) were projected to cause cascading it should mandate actual implementation of actions identified as needed to prevent the System from Cascading.

SDT Response:
The SDT agrees and has put these into a P8 planning event.

Clarification of Wording
Recommend wording for Parts 4.2.2.1 and 4.2.2.2 be similar to Requirement R3, Part 3.5 related to extreme events for the steady state portion of the Planning Assessment.

Recommend that Parts 4.2.2.1 and 4.2.2.2 be revised as follows:

- 4.2.2.1. List System deficiencies, the associated actions needed to prevent the System from Cascading.
- 4.2.2.2. Be reviewed in subsequent annual Planning Assessments for continued validity.

SDT Response:
The intent of the SDT was to have more analysis for a three phase fault followed by a protection failure as compared to other extreme events. It was not the intent of the SDT to require a CAP. Since FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended 3-phase faults be analyzed. Based on the reliability risk, the SDT decided to make the three-phase fault followed by a protection failure a P8 event with no Cascading allowed or a CAP requirement.

CAPs Limited to Protection System Projects

CAPs should be implemented to prevent Cascading; however, this should be limited to protection system projects.

SDT Response:
The SDT should not dictate to the TP or PC what the CAP has to be. The PC and/or TP needs to evaluate the best appropriate project to mitigate the violation.

Clarification of Wording

Parts 4.2.2, 4.2.2.1, and 4.2.2.2 “should not and do not mandate actual implementation of actions identified as needed to prevent the System from Cascading.” In fact, its comparison of the language to the language of those requirements associated with a mandatory CAP indicates that the language and obligations under Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are actually more robust and stringent. This comparison is provided above in Question 1. Commenter does not agree with the inclusion of Parts 4.2.2, 4.2.2.1, and 4.2.2.2. Commenter submits that these requirements together amount to an actual implementation requirement, and that the language is consistent with a required/ mandatory CAP. Irrespective to whether or not a Transmission Planner believes a capital project is required to be implemented by Parts 4.2.2.1 and 4.2.2.2, the compliance will be determined by the language in the standard. If the language in Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are essentially the same as that for a CAP, the requirement is essentially equivalent to CAP.

If Parts 4.2.2, 4.2.2.1, and 4.2.2.2 are not removed as requested above, to clarify the intent stated in this question, Commenter recommends the following revisions to the proposed language for Parts 4.2.2, 4.2.2.1, and 4.2.2.2:

4.2.2 If the analysis concludes there is Cascading caused by the occurrence of extreme events 2e-2h in the stability column, the TP and/or PC shall:

4.2.2.1 Document the list of System deficiencies and actions that could be taken to prevent the System from Cascading.

4.2.2.2 Review the list of System Deficiencies and potential actions to address such System deficiencies in subsequent annual Planning Assessments for continued validity

SDT Response:
The intent of the SDT was to have more analysis for a three-phase fault followed by a protection failure as compared to other extreme events. It was not the intent of the SDT to require a CAP. However, the SDT has decided to make a three-phase fault followed by a protection failure P8 planning event and require a CAP. This is because FERC Order No. 754 required a three-phase fault and the resultant SPCS and SAMS report indicated there was a reliability risk to the BPS.

Q2 Additional Comments

Additional Comment #1
Commenter believes that analyzing system performance when subject to "Extreme Events" is meant to provide a sense of where instability and/or Cascading could occur for the PC and/or TP to assess what actions could be developed to mitigate or reduce the potential impact. Such actions generally involve positioning the BES, adjusting outage plans, implementing operations strategies, developing a safe posture and preparing for resiliency plans, but not any capital investment projects. Note that this does not preclude the responsible entity from implementing any of these actions in its sole discretion, but it should not be mandated. Capital projects to address operational circumstances should not be mandated in a TPL standard. Further, requiring capital projects would exceed the scope of FERC Order 754 and 786 as well as the SAR.

SDT Response:
Per the NERC Glossary definition of CAP, a capital project is not required if implementing operations strategies mitigate the performance violation. The language in Parts 4.2.2.1 and 4.2.2.2 was intended to include operational strategies not just capital projects. However, the SDT decided to remove 4.2.2.1 and 4.2.2.2 and make a three phase fault followed by a protection failure a P8 planning event.

Additional Comment #2
Recommend the drafting team adds language to section 4.2.2.2 to clarify during the review process pertaining to the Planning Assessments for continued validity and implementation status that an adjustable time frame would always be taken into consideration.

SDT Response:
The SDT removed Part 4.2.2.2 and is making the three-phase fault followed by a protection failure a P8 planning event. The SDT also developed an implementation plan for TPL-001-5.

Additional Comment #3
Oftentimes the capital project may be a relay upgrade project which is relatively low cost compared to the benefits.

SDT Response:
The SDT agrees.

Question 3: Associated Timetable and Annual Review Requirement R4 Summary Response

3. Do you agree with the omission, as proposed in TPL-001-5 Requirement R4, Part 4.2, of a requirement similar to that of Requirement R2, Part 2.7, which states that the planned System shall continue to meet the performance requirements in Table 1 in subsequent Planning Assessments?

Requirement Omission

Commenter believes that the omission in 4.2 is necessary as there are not performance requirements in the Table for Extreme Events.

Commenter agrees that a requirement to ensure that Cascading does not occur in subsequent Planning Assessment given extreme events 2e-2h in the stability column should be omitted

SDT Response:
The SDT appreciates these comments. However, due to other comments received by the industry and since FERC Order No. 754 required a three-phase fault and the resultant SPCS and SAMS report indicated there was a reliability risk to the BPS, the SDT has decided to require a CAP for a three-phase fault followed by a protection failure results in Cascading or instability. This has been also made into a P8 event.

Implementation Timetable

Commenter disagrees with adding the 4.2.2.1 requirement to list a timetable for implementation of actions to reduce the likelihood or mitigate the consequences of any extreme contingence events, including extreme events 2e-2h and the 4.2.2.2 requirement to continue to review the validity and implementation status of the possible actions.

SDT Response:
The SDT appreciates these comments. However, due to the following:

- other comments received by the industry
- because FERC Order No. 754 required a three-phase fault and the resultant SPCS and SAMS report indicated there was a reliability risk to the BPS

The SDT has decided to require a CAP for a three-phase fault followed by a protection failure.

System Performance

Commenter believes that requirement 2.7 would cover system performance for the R4 requirements.

The planned system should always meet the performance requirements in Table 1 in any Planning Assessment that is performed. To the extent a Corrective Action Plan is developed for issues identified in one Planning Assessment and the issues go away in subsequent Planning Assessments due to changes in load forecasts or other drives of the original issue, elimination or modification of the Corrective Action Plan in the subsequent Planning Assessment should certainly be allowed, but the language above that states “the planned System shall continue to meet the performance requirements in Table 1 in subsequent Planning Assessments” seems unnecessary since the Table 1 requirements apply to all Planning Assessments.

If a system risk or vulnerability has been identified as a result of conducting a mandatory reliability assessment, Corrective Action Plan(s) must be developed which maintains system performance. Customers and regulators will not accept that a system deficiency was identified but not mitigated by a Transmission Planner when such an event occurs. If maintaining system performance following an event is not required, then performing an assessment of that event should not be required.

SDT Response:
The SDT agrees and has removed the confusion by making the three-phase fault followed by a protection failure a P8 planning event requiring a CAP to meet the associated performance requirements with Implementation Plan.

Q3 Additional Comments

Additional Comment #1
CAPs should not be required for a three-phase fault followed by a protection failure.

Commenter agrees that a corrective action plan should not be required for an extreme event. The 2e through 2h events referenced in Requirement R4, Part 4.2.2, however, should be planning events and, accordingly, corrective action plans should be required for them.

SDT Response:
The SDT disagrees, this is due to the fact that FERC Order No. 754 required a three-phase fault and the resultant SPCS and SAMS report indicated there was a reliability risk to the BPS. This is also supported by other industry comments. The SDT has decided to make a three-phase fault followed by a protection failure a P8 planning event.

Additional Comment #2
Commenter agrees that extreme events do not need the same level of requirements as Planning Events.

SDT Response:
The SDT disagrees, this is due to the fact that FERC Order No. 754 required a three-phase fault and the resultant SPCS and SAMS report indicated there was a reliability risk to the BPS. This is also supported by other industry comments. The SDT has decided to make a three-phase fault followed by a protection failure a P8 planning event.

Additional Comment #3
As mentioned in our response to Q2, our interpretation of Part 4.2.2 is that it requires the

implementation of corrective action plans –including capital projects– when analysis concludes there is Cascading. We support the implementation of corrective action plans.

If the drafting team considers that this is not the intent of the revision, and the implementation of capital projects IS NOT required, we propose that Part 4.2.2 be revised to make this clear.

SDT Response:
The SDT agrees and decided to make a three-phase fault followed by a protection failure a P8 planning event which removed much of the confusion in the industry.

Question 4: Footnote 13
Summary Response

4. Do you agree with including Table 1 Footnote 13 a., "[a] single protective relay which responds to electrical quantities, without an alternative that provides comparable Normal Clearing times, e.g., sudden pressure relaying", and its limitation to only the specific single protective relay and not to other elements of the associated Protection System?

The SDT paid considerable attention to the depth of the industry comments received regarding Footnote 13 (Questions 3, 4, and 5) and has sought to address general and specific industry comments with the following response. The most common comment noted the discrepancy between red-line version and clean version of the proposed draft; the SDT agrees and has corrected the Footnote 13 bullets to "a,b,c,d", not "1,2,3,4". One theme that was communicated by industry was to desire specificity about the Protection System components that must be redundant. The SDT seeks to make clear that the draft Footnote 13, as well as changes to the P5 and extreme events, do not prescribe any level of redundancy. Footnote 13 is not a definition of redundancy. On the contrary, Footnote 13 identifies the components of a Protection System that should be considered for redundancy and failures that may lead to Delayed Clearing, when Planning Coordinators and Transmission Planners simulate Contingencies for the purpose of analysis that supports TPL-001-5 annual Planning Assessments.

Sudden Pressure Relaying
Several stakeholders suggested removing "e.g. sudden pressure relaying" from Footnote 13a. It was suggested that this confusing language can appear to identify sudden pressure relays as a type of protective relays to be evaluated.

SDT Response: The SDT agrees that specific reference to sudden pressure relaying confuses the purpose of Footnote 13a, which is to focus on an alternative that provides comparable Normal Clearing times to a single protective relay which responds to electrical quantities. The proposed draft has been revised to omit this language.

Single Protective Relay Action
Similar to the comments suggesting that the SDT should define redundancy, some industry commenters suggested that the SDT should specify the actions taken by a single protective relay, instead of identifying

individual Protection System components when considering for redundancy under this standard. Relatedly, it was suggested that reference to a single protective relay should apply to a relay unit and not a relay element (multiple relay elements within a single relay unit are not redundant given a common failure, e.g., power supply).

SDT Response: The Footnote 13a in the proposed TPL-001-5 standard specifies the non-redundant components of a Protection System that the Planning Coordinator and Transmission Planner must consider. Therefore the PC and TP must determine how to properly simulate failures of non-redundant components of a Protection System, given the consideration of their constituent Protection Systems. The SDT does not desire to propose language that is overly prescriptive and instead desires that the focus remain on failures of non-redundant components of a Protection System that must be simulated for Delayed Fault Clearing.

Question 5: Footnote 13
Summary Response

5. Do you agree with the inclusion of Table 1 Footnote 13 b. & c. stipulation, "which is not monitored or not reported", and that it conveys the expectation that the monitoring and reporting is sufficient to result in prompt remediation addressing the failure status of the associated equipment?

Defining "Monitored" and "Reported"

The most-frequently provided industry comment to Question 5 indicated that "monitored" and "reported" were not sufficiently defined, such as in PRC-005-6 Tables 1-2, 1-4, and 2. Specifically, a desire was expressed for a reporting time stipulation when considering redundancy and how quickly corrective action could be enacted.

SDT Response: The SDT agrees with the industry comments and has modified the proposed Footnote 13b and 13c to language similar to that in the Standards Authorization Request (SAR) proposed following the joint SAMS/SPCS report: "not monitored such that alarms are centrally reported (i.e., reported within 24 hours of detecting an abnormal condition to a location where corrective action can be initiated)." The SDT simplified the suggested language to "not monitored or not reported at a Control Center." It is well understood that a Control Center hosts operating personnel that monitor the Bulk Electric System (BES) in real-time to perform reliability tasks, so the SDT did not believe specifying a reporting or correction initiation timeframe was necessary. Separately, reference to a single station dc supply was added by the SDT to 13c to align with the Protection System defined term.

Communication Systems

Some industry commenters suggested that communication systems referenced by Footnote 13b should be limited to just those used for critical/crucial Normal Clearing times.

SDT Response: Given the increasing importance of communication-aided Protection Systems (e.g., pilot protection schemes, direct transfer tripping schemes, permissive transfer tripping schemes, etc.), the proper operation of the communication system must be considered when considering potential single point of failure (SPF) components of Protection Systems. Although the SAMS/SPCS report noted that a SPF in a communication system posed a lower level of risk, the drafting team augmented the SAMS/SPCS recommendations to include reference to the subset of communication systems that are part of a communication-aided Protection System, necessary where the performance of that Protection System is required to achieve Transmission System Planning Performance Requirements, enumerated in Table 1 of TPL-001-5. In other words, a communication-aided Protection System that may experience a SPF, causing it to operate improperly or not at all leading to Delayed Clearing, must be considered as part of non-redundancy. The SDT concluded that the failure of communication-aided Protection Systems may take many forms; however, by alarming and monitoring these systems, the overall risk of impact to the BES is reduced to an acceptable level. Most new Protection Systems deployed in the industry include communication-aided protection with component and communication failure alarms monitored at centralized Control Centers. This alarm monitoring is similar to the requirement associated with station DC supplies. Therefore, this requirement is more applicable to legacy systems that need communication-aided Protection Systems to meet performance requirements of the TPL-001-5 standard. Further, the SDT does not believe that critical or crucial clearing times are pertinent to the Planning Coordinator or Transmission Planner when determining how long to simulate a fault until it clears. In other words, the critical clearing time is a result of analysis, not a precondition of the analysis (such as considerations of Protection System component redundancy).

Protective Functions

For consistency amongst the non-redundant components of a Protection System that must be considered as part of Footnote 13, the protective functions associated with a single dc supply should refer to Normal Clearing.

SDT Response: The SDT agrees with the industry comment and has added reference to Normal Clearing to Footnote 13c and 13d for consistency and clarity.

Q5 Additional Comments

Additional Comment #1

Some industry stakeholders believe that preventive maintenance per PRC-005 provides reasonable and sufficient assurance for detection and handling “open circuit” conditions, implying that this stipulation in Footnote 13c should be omitted.

SDT Response: The SDT agrees that PRC-005 establishes maintenance practices that may significantly reduce the likelihood of a single point of failure in a dc supply serving protective functions, however this may not eliminate its occurrence and may lead to Delayed Fault Clearing. The SDT proposed Footnote 13c is consistent with the SAMS/SPCS report recommendations and the Project 2015-10 SAR.

Question 6: Footnote 13
Summary Response

6. Do you agree with the inclusion of Table 1 Footnote 13 d., and that it, in conjunction with defined terms, identifies what constitutes all of the elements of, "A single control circuitry associated with protective functions including the trip coil(s) of the circuit breakers or other interrupting devices."?

Definition of Control Circuitry

The most common industry comments regarding Footnote 13d suggested the definitions of control circuitry remains vague; that the demarcation of supply and control circuitry was vague; and, suggested aligning the Footnote 13d language closer to that recommended in the SPCS report.

SDT Response: The SDT intended single DC supply to refer to the entire set of equipment that comprises the DC source supplying power to Protection System components necessary for Normal Clearing. In other words, the SDT sought to specify that, within the entire set of equipment comprising the single DC supply, a failure of a piece of equipment that causes the single DC supply to be unable to source power to the protective functions necessary for Normal Clearing must be considered as part of Footnote 13. Relatedly, the SDT agrees that a typical station battery bank is only one part of the single DC supply. Further, a failure of a station battery may be masked for short time by the AC-sourced station battery charger. However, the SDT did not prescribe specific DC supply design configurations. Instead, the SDT emphasized that the single DC supply must be considered for susceptibility to SPF as part of Footnote 13. To clarify Footnote 13d, the SDT has revised it to explicitly include auxiliary relays and lockout relays in the control circuitry, as well as specify the circuitry components to consider extends through and including the trip coils.

Trip Coil Failure

Some industry commenters suggested that a failure in a non-redundant single trip coil that results in a breaker not acting properly is covered by breaker failure (P4 events). Similarly, it was suggested to replace references to interrupting device trip coils with reference to auxiliary relays in the interrupting device control circuity given that this is more severe and simulation of a single interrupting device trip coil failure is expected to be the same as the simulation of a P4.

SDT Response: While trip coil monitoring devices are commonly available to give awareness of potential trip coil failure, the SDT believes monitoring trip coil failure or relay trouble indication is insufficient to ensure that a SPF is not present within a single control circuit. Similarly, DC undervoltage relaying or other control circuit continuity monitoring may indicate a problem with part of the DC control circuit, but may not give awareness of SPF risks such as serial tripping devices (ANSI #86 and #94 devices). Therefore, The SDT did not incorporate a monitoring provision into Footnote 13d and intends for non-redundant components within the DC control circuitry of a Protection System to be considered as part of Footnote 13.

Question 7: Known Outages
Summary Response

7. Do you agree with the proposed changes to Requirement 1, Part 1.1.2 that modify which known outages shall be represented in System models from those "with a duration of at least six months" to those *selected by the Planning Coordinator (PC)/Transmission Planner (TP) "in consultation with" their Reliability Coordinators (RCs)?*

Selecting Outages in Consultation with Reliability Coordinator

The majority of industry respondents commented that selecting outages in consultation with their Reliability Coordinators was problematic and offered alternative suggestions.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

Roles and Responsibilities for Reliability Coordinator and Transmission Planner

Several industry respondents commented that if the coordination language is retained clarity needs to be added to better define "consultation". The roles and responsibilities need to be spelled out including establishing criteria for outages and resolving conflicts between the RC and TP.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

Outages in the Near Term Planning Horizon

Several industry commenters believed that outages in the near term planning horizon should remain within the auspicious of the TPL standard and not in the IRO arena.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

IRO-017

Several industry commenters believed IRO-017 should be the primary vehicle to include planned outages in the near term planning horizon.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

Six Month Outage Duration

Several industry commenters suggested the directive could be addressed by changing the 6 month outage period to something like "outages spanning the entire season under study" (or other outages as determined by the TP/PC)

SDT Response: The SDT believes that the time duration of a known outage does not necessarily correlate with the significance of outage. The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1 part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

Q7 Additional Comments

Additional Comment #1

Several commenters requested event clarification – standard specifies that only P1 events should be run on the cases with these outages in place, do we remove them for the other studies

SDT Response: Requirement R2, Part 2.4.3 requires new maintenance outages that have met the TP/PC requirement for studies to be conducted for P1 events only. How, or if, an entity choses to incorporate outages when performing additional analysis is not a NERC TPL standard requirement.

Additional Comments #2

One commenter responded with a minor changes Lower-case the term "Off Peak".

SDT Response: The capitalized term "Off-Peak" are in Parts 2.1.3 and 2.4.3 that have already been approved by industry. The SDT is not proposing to change those requirements.

Question 8: Applicability
Summary Response

8. Do you agree with omitting the Reliability Coordinator (RC) from the applicability of the TPL-001-5 standard given that Requirement R1, Part1.1.2 requires consultation between the TP/PC and the RC to determine which known outages to select for representation in System models?

Regional Differences

The range of industry comments to question 7 indicates there are substantial regional differences in the methods and procedures to address outages in the near term planning horizon. The majority of industry respondents commented that Reliability Coordinator involvement is not necessary (this standard only applies to TP and PCs) or move RC duty details to IRO-017 (then delete from TPL).

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

Reliability Coordinator Applicability

The range of industry comments to question 7 indicates there are substantial regional differences in the methods and procedures to address outages in the near term planning horizon. The significant minority of industry respondents commented that if “consultation” with RC is not removed, then add the RC to the applicability portion.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon.

Q8 Additional Comments

Several comments that were duplicative of comments received in question 7 including-Specify roles and responsibilities; Revise IRO-017-1 to address FERC directive; and Move the reporting requirement in IRO-017-1 R3 to TPL-001-5 instead.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon. Modifications to IRO-017 are not within the scope of the approved Project 2015-10 SAR.

Question 9: Outage Coordination
Summary Response

9. FERC Order No. 786 Paragraphs 40-45 direct modification to address significant planned maintenance outages with durations less than 6 months in planning assessments. Are you aware of an existing standard/requirement, consistent with industry practice and applicability that requires review and coordination of significant known maintenance outages less than 6 months in duration for inclusion in System models (TPL 001-4 Requirement R1 Part R1.1.2)?

Regional Differences Concerning Outage Coordination (IRO-017)

The range of industry comments to question 7 and 9 indicates there are substantial regional differences in the methods and procedures to address outages in the near term planning horizon. The majority of industry respondents pointed to IRO-017 to tighten up coordination of significant outages that are less than 6-month duration; expressed that coordination is already being done through various mechanism; or the directive predates IRO-017-1 and isn’t relevant anymore.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of know maintenance outages in the near term planning horizon. Modifications to IRO-017 are not within the scope of the approved Project 2015-10 SAR.

Regional Differences Concerning Outage Coordination (MOD-032) and Applicability of Transmission Owner and Generator Owner

The range of industry comments to question 7 and 9 indicates there are substantial regional differences in the methods and procedures to address outages in the near term planning horizon. Several industry respondents suggested to modify MOD-032 such that known outages are included in the data submitted for TPL.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the Near-Term Transmission Planning Horizon. Accordingly the SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of known maintenance outages in the near term planning horizon. MOD-032 does not specifically address how outages are communicated, however the TP and PC may require Transmission Owner (TO) and Generator (GO) to provide outage related data.

Question 10: Implementation Plan
Summary Response

10. Do you agree with the 36 month implementation period to address all Requirements except for Requirement R4, Part 4.2, and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.

Existing substations and new substations

There is a suggestion to grandfather existing substations and any new requirements would apply to new substations when they are built.

SDT Response: FERC Order No. 754 analysis and the resultant SPCS and SAMS report indicated there is a reliability risk to the BPS caused by single point of failures with existing Protection Systems. These reliability concerns need to be addressed for the existing and planned Protection Systems. The purpose of the Implementation Plan is to allow for identification and mitigation of all Protection System single points of failures to meet performance requirements, whether existing or planned.

Proposed P5 event / footnote 13

Some commenters disagree with a 36 month implementation period because of the ambiguity in the proposed P5 event / footnote 13. Additionally, larger utilities suggested the Implementation Plan be extended to 48 month.

SDT Response: The SDT has addressed ambiguity concerns in Footnote 13 language previously in Questions 4 through 6 and has modified Footnote 13. The SDT feels that 36 months are adequate to complete first set of studies. The implantation plan allows for additional time to develop a CAP.

Stability Analysis for Spare Equipment

Addressing all new requirements except 4.2 and 2.7 which would include the stability analysis for spare equipment and developing a process for selecting known outages and establishing coordination with protection engineers. Stability analysis is the most time consuming part of the planning assessments.

SDT Response: The SDT agrees and has revised the implementation.

Question 11: Implementation Plan Summary Response

11.Do you agree with the 60 month implementation plan for Requirement 4, Part 4.2 and Requirement 2, Part 2.7 associated with the modified P5 events further defined in the redline changes to Footnote 13.?

The Additional 24-months Too Short

The additional 24-months to implement any resulting Corrective Action Plans for P5 events may be too short.

SDT Response: The additional 24 months is to only identify appropriate Corrective Action Plan and establish the associated timetables for completion.

72-months Implementation Recommended

A 72-month implementation plan would be preferable for the development of Corrective Action Plans to address newly-added studies involving single point of failure on Protection Systems.

SDT Response: The SDT disagrees. The revised implementation period provides Planning Coordinators and Transmission Planners with 36 months to update their annual Planning Assessments to include the new System models and studies required by the standard. In addition, the implementation plan includes an additional 24-month period for the development of Corrective Action Plans under TPL-001-5 to address newly added studies involving single points of failure on Protection Systems. Furthermore, in the event that an Operating Procedure, Non-Consequential Load Loss or curtailment of Firm Transmission Service is insufficient to meet performance requirements, the implementation plan includes an additional 36 months to meet the performance requirements of Table 1 for revisions to P5, and the addition of P8.

Question 12: Cost Effectiveness Summary Response

12. In looking at all proposed recommendations from the standard drafting team, are the proposed changes a cost effective approach which meets the FERC directives? (see Cost Effectiveness Background Document)

CAP for Extreme Events Low Probability Event not economical:
Several industry comments indicate that proposed TPL-001-5 Requirement R4, Parts 4.2.2.1 and 4.2.2.2, including an implementation timetable and annual review of implementation status for the extreme stability 2e-2h event contingencies go significantly beyond obligations for all other extreme events, and it is not economically justifiable and cost effective to require a CAP for low probability events.

SDT Response: FERC Order No. 754 resulted in follow-up analysis by the industry and the SPCS and SAMS assessment of additional analysis recommended three-phase faults be analyzed. Based on the reliability risk, the SDT decided to make the three-phase fault followed by a protection failure a P8 event with no cascading allowed. In view of the addition of P8 events, industry stakeholders will have the opportunity to re-evaluated cost effectiveness in the next posting.

Six Month Outage Duration review
Several industry comments indicate that Transmission Planners (TP) performing an annual study review of outages less than six months have redundancies associated with outage coordination and does not represent a cost effective approach.

SDT Response: The SDT has revised Requirement 1, Part 1.1.2 to recognize and codify the various means that TPs and PCs currently employ to consider the impact of known maintenance outages in the near term planning horizon. Industry stakeholders will have the opportunity to re-evaluate cost effectiveness in the next posting.

Q12 Additional Comment
Requiring a fully-redundant control circuitry without due consideration of status monitoring combined with periodic independent component testing is duplicative for system reliability and is not the most cost-effective option to address the FERC directive. The cost-effective solution is to include the allowance for excluding control circuitry with monitoring from Footnote 13d.

SDT Response: The SDT disagrees with the comment because continuity monitoring of the control circuits may not give awareness of single point of failure risks. Therefore, the SDT did not incorporate a monitoring provision into Footnote 13d and intends for non-redundant components within the control circuitry of a Protection System to be considered as part of Footnote 13d. Please refer to Question 6 response.

Question 13: Governing Documents
Summary Response

13. Are you aware of any other governing documents that could be in conflict with the current proposal for this draft of the standard?

Coordination between the TPL-001-5 and the new FAC-015 standards

The industry consider that the new FAC-015 requirements with respect to the system operating limits should be used in planning assessments and need to be included within TPL-001-5.

SDT Response: The new FAC-015 requirements with respect to the system operating limits to be used in planning assessments cannot be included within TPL-001-5 because these are not part of the objectives of the Project 2015-10 Single Point of Failure SAR. The request to coordinate the standards FAC-015 and TPL-001 with respect to the system operating limits to be used in planning assessments belong in a new SAR and must be addressed to NERC.

Multiple NERC definitions of acceptable types of redundancy of Protection System

The difference between the protection system redundancy definition in the 2009 NERC document "Protection System Reliability – Redundancy of Protection", as well as the redundancy requirements described in PRC-012-2, and theTPL-001-5 footnote 13 will likely cause confusion in industry.

SDT Response: There is a difference between the Protection System redundancy definition in the documents mentioned above and footnote 13 of TPL-001-5. The purpose of the TPL-001 modified footnote 13 is to specify which non-redundant components of a Protection System to be considered for the Single Point of Failure analysis. It was not intended to define the Protection System redundancy. The inclusion of some elements of a protection system but not all, aligns with the SAMS and SPCS recommendations.

Disconnection between operations and planning

The IRO-017 already defines the process for studying outages within the Operational Planning Horizon. The industries consider that the maintenance outages should be evaluated in the Operating Horizon, if not, a conflict can be created between the two standards TPL-001-5 and IRO-017-1.

SDT Response: The planned outages studied in TPL-001 are provided to the RC through the Near-Term Planning Assessment to jointly develop solutions for identified issues or conflicts with planned outages as part of the outage coordination process of IRO-017. Therefore, there is no conflict between TPL-001 and IRO-017.

Implementation of corrective actions might require capital projects and additional infrastructure

Requiring implementation of corrective actions which include capital projects and additional infrastructure would contradict the Energy Policy Act of 2005 and directly conflicts with some provincial regulations.

SDT Response: Reliable operation of the BPS is required by the Federal Legislation. Requirement 2.7.1 allows solutions to be developed which don't necessarily require construction of additional generation or transmission capacity. The SDT proposes to add a new P8 Planning Event to "Table 1 – Steady State and Stability Performance Planning Events", in order to include a 3-phase fault and failure of a non-redundant component of a Protection System.

Question 14: Other Considerations
Summary Response

14. Do you have any other general recommendations/considerations for the drafting team?

Paragraph 81

Requirements R5, R6, R7, and R8 fall under such criteria

SDT Response: The SDT disagrees that Requirement 5, 6, 7,-8 meet the Paragraph 81 criteria.

NERC Project to address FERC Directives

Commenter suggests that objectives outlined in the FERC Directives could be accomplished without the need to revise the standard in this manner. The objectives could be met in the form of a NERC project or initiative requesting that these assessments/studies be done in 10% or 20% intervals over a set period of time, and the data submitted to NERC for its review. We feel that requiring these objectives in a standard, with the ever changing configuration of the system, would require that this work as proposed be done every year, which would be extremely burdensome. We recommend that the studies and assessments that will be required would be better suited outside of the NERC standards.

SDT Response: Thank you for your comment. A standards project was required to address the FERC directives.

TPL-001-5 R4, Part 4.2.2.2 including extreme event 2e-2h

Many of the comments submitted for Question 14 paralleled or echoed the comments from Questions 1-3. Additionally commenters proposed specific language suggestions for certain sections.

SDT Response: When possible the SDT considered the language suggestions. Please see the revised standard to see if your specific suggestion or a close proximity was incorporated into the new language. For the comments that were submitted in Question 14 that paralleled or echoed the comments from Questions 1-3, please see the comments from the SDT provided in Questions 1-3.

Economic Impacts of Extreme Events

Commenter suggested the drafting team should revisit the economic impacts of the proposed changes, specifically those concerning extreme events.

SDT Response: See response for Question 12.

TPL-001-5 Footnote 13

Many of the comments submitted for Question 14 paralleled or echoed the comments from Questions 4-6. Additionally commenters proposed specific language suggestions for certain sections.

SDT Response: When possible, the SDT considered the language suggestions. Please see the revised standard to see if your specific suggestion or a close proximity was incorporated into the new language.

For the comments that were submitted in Question 14 that paralleled or echoed the comments from Questions 4-6, please see the comments from the SDT provided in Questions 4-6.

TPL-001-5 TP/PC Coordination with RC, Outage Coordination

Many of the comments submitted for Question 14 paralleled or echoed the comments from Questions 7-9. Additionally commenters proposed moving requirements both to and from IRO-017. Several stakeholders expressed concerns that selecting outages in consultation with their Reliability Coordinators was problematic and offered alternative suggestions.

SDT Response: The range of industry comments to this question indicate there are substantial regional differences in the methods and procedures to address outages in the near term planning horizon. Those differences contribute to a legitimate difficulty in designing a cost-effective continent wide standard addressing the FERC directive. For the comments that were submitted in Question 14 that paralleled or echoed the comments from Questions 7-9, please see the comments from the SDT provided in Questions 7-9.

Spare Equipment Strategy in Stability Study

The new version of the standard has included the spare equipment strategy into the stability portion of the assessment. This is unnecessary because this analysis is captured in the normal stability study. For example, a transformer qualifies as equipment with lead time greater than a year. The loss of the transformer is captured in the normal stability contingency analysis. If this analysis resulted in an unacceptable response, the scenario would be investigated to determine a mitigation (like using a spare transformer in its place).

SDT Response: The existing language in the standard requires a CAP. Loss of long-lead items are studied. No changes to the language is necessary.

Monitoring of Protection System

If monitoring of Protection System components is counted for purposes of TPL-001-5, is it the drafting team's intent that an entity would be obligated to maintain the alarming paths and monitoring systems under PRC-005-6 (Requirement R1, Part 1.2, and Table 2)? An entity should be allowed to consider monitoring for purposes of TPL-001-5 but treat the associated Protection System component(s) as unmonitored for purposes of PRC-005-6.

SDT Response: See response to Question 6.

Spare Equipment Strategy

The proposed changes to the Spare Equipment Strategy paragraph (2.4.5) create an unclear requirement for determining if acceptable performance has been met. The revised language introduces a "more severe System impact" standard of performance. This begs the question, "More severe than what?

SDT Response: This exists in the current of the standard and it is up to the PC and TP to determine what is more severe.

Linking Standards

Perhaps this is an opportunity to link TPL-001-5 and PRC-023-4 into a single assessment?

SDT Response: the TP and PC can take the Planning Assessment and apply to PRC-023-4. No link is required

Models Developed under MOD-032

The timing of models developed under MOD-032 sometime make it difficult to have an exact "year five" model. R2.1.1 could be more flexible – similar to 2.1.2.

SDT Response: The TP and PC can request data for any year that they need.

Standard Revision

In section 2.4., the last sentence should be adjusted to look more like the last sentence of section 2.2.

SDT Response: Thank you for your comment. This is not in the scope of the SAR.
NERC Glossary of Terms

Footnote 12

Regarding Table 1, if the performance requirements (steady state / stability) are not being met, AND, if Table 1 indicates that non-consequential load loss and interruption of Firm Transmission Service are allowed, is a specific corrective action plan required as per Requirement 2.7 (assuming that non-consequential load loss and/or interruption of Firm Transmission Service would allow for meeting the performance requirements)? This question relates to a scenario where Footnote 12 does not apply. A general recommendation is to clarify within the standard whether or not a specific corrective action plan is required to be documented, as per Requirement 2.7, in the Planning Assessment for this scenario (i.e. performance requirements are not being met and Footnote 12 does not apply).

SDT Response: Thank you for your comment. This is not in the scope of the SAR.

Revision of PRC Standard

An alternative first step should have been in a PRC Standard to address the concerns in reference to Single Point Failure. Furthermore, there could be a potential disconnect between the Transmission Planner and Protection Engineers by placing this only in a Planning Standard. Also, we recommend that the draft team includes the Transmission Owner (TO) and Generator Owner (GO) in the applicability section, along with an additional requirement specifying that the TO and GO should provide pertinent data (e.g., contingency definitions, elements tripped) upon request by the PC in order to assess the impact of Single Point of Failure in their assessments.

SDT Response: Thank you for your comment. This is not in the scope of the SAR.

Industry Segments

The Industry Segments are:

1 — Transmission Owners

2 — RTOs, ISOs

3 — Load-serving Entities

4 — Transmission-dependent Utilities

5 — Electric Generators

6 — Electricity Brokers, Aggregators, and Marketers

7 — Large Electricity End Users

8 — Small Electricity End Users

9 — Federal, State, Provincial Regulatory or other Government Entities

10 — Regional Reliability Organizations, Regional Entities

Standard Development Timeline

This section is maintained by the drafting team during the development of the standard and will be removed when the standard is adopted by the NERC Board of Trustees (Board).

Description of Current Draft

This is the first draft of the proposed standard.

Completed Actions	Date
Standards Committee approved Standard Authorization Request (SAR) for posting	October 29, 2015
SAR posted for comment	May 26 – June 24, 2016
Informal Comment Period	April 25 – May 24, 2017
45-day formal comment period with initial ballot	September 8 – October 23, 2017

Anticipated Actions	Date
45-day formal comment period with additional ballot	February 2018
10-day final ballot	May 2018
Board adoption	August 2018

New or Modified Term(s) Used in NERC Reliability Standards

This section includes all new or modified terms used in the proposed standard that will be included in the *Glossary of Terms Used in NERC Reliability Standards* upon applicable regulatory approval. Terms used in the proposed standard that are already defined and are not being modified can be found in the *Glossary of Terms Used in NERC Reliability Standards*. The new or revised terms listed below will be presented for approval with the proposed standard. Upon Board adoption, this section will be removed.

Term(s):

None.

Upon Board adoption, the rationale boxes will be moved to the Supplemental Material Section.

A. Introduction

1. **Title:** **Transmission System Planning Performance Requirements**

2. **Number:** **TPL-001-5**

3. **Purpose:** Establish Transmission system planning performance requirements within the planning horizon to develop a Bulk Electric System (BES) that will operate reliably over a broad spectrum of System conditions and following a wide range of probable Contingencies.

4. **Applicability:**

   4.1. Functional Entity

   4.1.1. Planning Coordinator.

   4.1.2. Transmission Planner.

5. **Effective Date: See Implementation Plan.**

B. Requirements and Measures

R1. Each Transmission Planner and Planning Coordinator shall maintain System models within its respective area for performing the studies needed to complete its Planning Assessment. The models shall use data consistent with that provided in accordance with the MOD-032 standard, supplemented by other sources as needed, including items represented in the Corrective Action Plan, and shall represent projected System conditions. This establishes Category P0 as the normal System condition in Table 1. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

1.1. System models shall represent:

1.1.1. Existing Facilities.

1.1.2. Known outage(s) of generation or Transmission Facility(ies) scheduled in the Near-Term Transmission Planning Horizon selected for analyses pursuant to Requirement R2, Parts 2.1.3 and 2.4.3 only. Known outage(s) shall be selected according to an established procedure or technical rationale that, at a minimum:

1.1.2.1. Includes known outage(s) that are expected to result in Non-Consequential Load Loss for P1 events in Table 1 when concurrent with the selected known outage(s); and

1.1.2.2. Does not exclude known outage(s) solely based upon the outage duration.

1.1.3. New planned Facilities and changes to existing Facilities.

1.1.4. Real and reactive Load forecasts.

1.1.5. Known commitments for Firm Transmission Service and Interchange.

1.1.6. Resources (supply or demand side) required for Load.

M1. Each Transmission Planner and Planning Coordinator shall provide evidence, in electronic or hard copy format, that it is maintaining System models within their respective area, using data consistent with MOD-032 including items represented in the Corrective Action Plan, representing projected System conditions, and that the models represent the required information in accordance with Requirement R1.

R2. Each Transmission Planner and Planning Coordinator shall prepare an annual Planning Assessment of its portion of the BES. This Planning Assessment shall use current or qualified past studies (as indicated in Requirement R2, Part 2.6), document assumptions, and document summarized results of the steady state analyses, short circuit analyses, and Stability analyses. *[Violation Risk Factor: High] [Time Horizon: Long-term Planning]*

2.1. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by current annual studies or qualified past studies as indicated in Requirement R2, Part 2.6. Qualifying studies need to include the following conditions:

2.1.1. System peak Load for either Year One or year two, and for year five.

2.1.2. System Off-Peak Load for one of the five years.

2.1.3. P1 events in Table 1 expected to produce more severe System impacts on its portion of the BES, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.1.4. For each of the studies described in Requirement R2, Parts 2.1.1 and 2.1.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in System response:

- Real and reactive forecasted Load.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.
- Controllable Loads and Demand Side Management.
- Duration or timing of known Transmission outages.

2.1.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. The analysis shall be performed for the P0, P1, and P2 categories identified in Table 1 with the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.2. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the steady state analysis shall be assessed annually and be supported by the following annual current study, supplemented with qualified past studies as indicated in Requirement R2, Part 2.6:

2.2.1. A current study assessing expected System peak Load conditions for one of the years in the Long-Term Transmission Planning Horizon and the rationale for why that year was selected.

2.3. The short circuit analysis portion of the Planning Assessment shall be conducted annually addressing the Near-Term Transmission Planning Horizon and can be supported by current or past studies as qualified in Requirement R2, Part 2.6. The analysis shall be used to determine whether circuit breakers have interrupting capability for Faults that they will be expected to interrupt using the System short circuit model with any planned generation and Transmission Facilities in service which could impact the study area.

2.4. For the Planning Assessment, the Near-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed annually and be supported by current or past studies as qualified in Requirement R2, Part2.6. The following studies are required:

2.4.1. System peak Load for one of the five years. System peak Load levels shall include a Load model which represents the expected dynamic behavior of Loads that could impact the study area, considering the behavior of induction motor Loads. An aggregate System Load model which represents the overall dynamic behavior of the Load is acceptable.

2.4.2. System Off-Peak Load for one of the five years.

2.4.3. P1 events in Table 1 expected to produce more severe System impacts on its portion of the BES, with known outages modeled as in Requirement R1, Part 1.1.2, under those System peak or Off-Peak conditions when known outages are scheduled.

2.4.4. For each of the studies described in Requirement R2, Parts 2.4.1 and 2.4.2, sensitivity case(s) shall be utilized to demonstrate the impact of changes to the basic assumptions used in the model. To accomplish this, the sensitivity analysis in the Planning Assessment must vary one or more of the following conditions by a sufficient amount to stress the System within a range of credible conditions that demonstrate a measurable change in performance:

- Load level, Load forecast, or dynamic Load model assumptions.
- Expected transfers.
- Expected in service dates of new or modified Transmission Facilities.
- Reactive resource capability.
- Generation additions, retirements, or other dispatch scenarios.

2.4.5. When an entity's spare equipment strategy could result in the unavailability of major Transmission equipment that has a lead time of one year or more (such as a transformer), the impact of this possible unavailability on System performance shall be assessed. Based upon this assessment, an analysis shall be performed for the selected P1 and P2 category events identified in Table 1 for which the unavailability is expected to produce more severe System impacts on its portion of the BES. The analysis shall simulate the conditions that the System is expected to experience during the possible unavailability of the long lead time equipment.

2.5. For the Planning Assessment, the Long-Term Transmission Planning Horizon portion of the Stability analysis shall be assessed to address the impact of proposed material generation additions or changes in that timeframe and be supported by current or past studies as qualified in Requirement R2, Part2.6 and shall include documentation to support the technical rationale for determining material changes.

2.6. Past studies may be used to support the Planning Assessment if they meet the following requirements:

2.6.1. For steady state, short circuit, or Stability analysis: the study shall be five calendar years old or less, unless a technical rationale can be provided to demonstrate that the results of an older study are still valid.

2.6.2. For steady state, short circuit, or Stability analysis: no material changes have occurred to the System represented in the study. Documentation to support the technical rationale for determining material changes shall be included.

2.7. For planning events shown in Table 1, when the analysis indicates an inability of the System to meet the performance requirements in Table 1, the Planning Assessment shall include Corrective Action Plan(s) addressing how the performance requirements will be met. Revisions to the Corrective Action Plan(s) are allowed in subsequent Planning Assessments but the planned

System shall continue to meet the performance requirements in Table 1. Corrective Action Plan(s) do not need to be developed solely to meet the performance requirements for a single sensitivity case analyzed in accordance with Requirements R2, Parts 2.1.4 and 2.4.3. The Corrective Action Plan(s) shall:

2.7.1. List System deficiencies and the associated actions needed to achieve required System performance. Examples of such actions include:

- Installation, modification, retirement, or removal of Transmission and generation Facilities and any associated equipment.
- Installation, modification, or removal of Protection Systems or Remedial Action Schemes.
- Installation or modification of automatic generation tripping as a response to a single or multiple Contingency to mitigate Stability performance violations.
- Installation or modification of manual and automatic generation runback/tripping as a response to a single or multiple Contingency to mitigate steady state performance violations.
- Use of Operating Procedures specifying how long they will be needed as part of the Corrective Action Plan.
- Use of rate applications, DSM, new technologies, or other initiatives.

2.7.2. Include actions to resolve performance deficiencies identified in multiple sensitivity studies or provide a rationale for why actions were not necessary.

2.7.3. If situations arise that are beyond the control of the Transmission Planner or Planning Coordinator that prevent the implementation of a Corrective Action Plan in the required timeframe, then the Transmission Planner or Planning Coordinator is permitted to utilize Non-Consequential Load Loss and curtailment of Firm Transmission Service to correct the situation that would normally not be permitted in Table 1, provided that the Transmission Planner or Planning Coordinator documents that they are taking actions to resolve the situation. The Transmission Planner or Planning Coordinator shall document the situation causing the problem, alternatives evaluated, and the use of Non-Consequential Load Loss or curtailment of Firm Transmission Service.

2.7.4. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

2.8. For short circuit analysis, if the short circuit current interrupting duty on circuit breakers determined in Requirement R2, Part 2.3 exceeds their Equipment Rating, the Planning Assessment shall include a Corrective Action Plan to address the Equipment Rating violations. The Corrective Action Plan shall:

2.8.1. List System deficiencies and the associated actions needed to achieve required System performance.

2.8.2. Be reviewed in subsequent annual Planning Assessments for continued validity and implementation status of identified System Facilities and Operating Procedures.

M2. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of its annual Planning Assessment, that it has prepared an annual Planning Assessment of its portion of the BES in accordance with Requirement R2.

R3. For the steady state portion of the Planning Assessment, each Transmission Planner and Planning Coordinator shall perform studies for the Near-Term and Long-Term Transmission Planning Horizons in Requirement R2, Parts 2.1, and 2.2. The studies shall be based on computer simulation models using data provided in Requirement R1. *[Violation Risk Factor: Medium] [Time Horizon: Long-term Planning]*

3.1. Studies shall be performed for planning events to determine whether the BES meets the performance requirements in Table 1 based on the Contingency list created in Requirement R3, Part 3.4.

3.2. Studies shall be performed to assess the impact of the extreme events which are identified by the list created in Requirement R3, Part 3.5.

3.3. Contingency analyses for Requirement R3, Parts 3.1 & 3.2 shall:

3.3.1. Simulate the removal of all elements that the Protection System and other automatic controls are expected to disconnect for each Contingency without operator intervention. The analyses shall include the impact of subsequent:

3.3.1.1. Tripping of generators where simulations show generator bus voltages or high side of the generation step up (GSU) voltages are less than known or assumed minimum generator steady state or ride through voltage limitations. Include in the assessment any assumptions made.

3.3.1.2. Tripping of Transmission elements where relay loadability limits are exceeded.

3.3.2. Simulate the expected automatic operation of existing and planned devices designed to provide steady state control of electrical system quantities when such devices impact the study area. These devices may include equipment such as phase-shifting transformers, load tap changing transformers, and switched capacitors and inductors.

3.4. Those planning events in Table 1, that are expected to produce more severe System impacts on its portion of the BES, shall be identified and a list of those Contingencies to be evaluated for System performance in Requirement R3, Part 3.1 created. The rationale for those Contingencies selected for evaluation shall be available as supporting information.

3.4.1. The Planning Coordinator and Transmission Planner shall coordinate with adjacent Planning Coordinators and Transmission Planners to ensure that Contingencies on adjacent Systems which may impact their Systems are included in the Contingency list.

3.5. Those extreme events in Table 1 that are expected to produce more severe System impacts shall be identified and a list created of those events to be evaluated in Requirement R3, Part 3.2. The rationale for those Contingencies selected for evaluation shall be available as supporting information. If the analysis concludes there is Cascading caused by the occurrence of extreme events, an evaluation of possible actions designed to reduce the likelihood or mitigate the consequences and adverse impacts of the event(s) shall be conducted.

M3. Each Transmission Planner and Planning Coordinator shall provide dated evidence, such as electronic or hard copies of the studies utilized in preparing the Planning Assessment in accordance with Requirement R3.
